The wide drills should be three or four feet apart, or at sufficient distance to admit of pruning and cultivation between them, and to give room for workmen to pass when hoeing and weeding the plants. Frequent stirring of the soil between the rows with plow and cultivator during the summer, materially increases the growth of the plants, as well as facilitates the emission of side or lateral roots. At the end of the first season, or certainly not later than the second, the plants should be dug up. This may be done very rapidly with spades, or faster and better with a tree digger represented in figure 1. This very handy implement passes under the plants, cuts off the tap-root if long, and at the same time leaves them standing upright in the row, from whence they can be readily pulled up by men following the digger, or left to be taken up

when wanted. Having used one of these implements for many years, I can speak from experience of its value, especially for lifting seedlings that have very long and coarse tap-roots, like the black walnut, hickories, and similar kinds, as shown in figure 2.

Fig. 1.—THE TREE DIGGER.

After the plants have been lifted, the long tap-root should be shortened if it has not been cut off by the digger. Some of the nut trees, like those mentioned above, will throw down a central or tap-root to the depth of two or three feet the first season, while the stem above may not be more than a foot high. Figure 2 represents an average specimen of a one-year-old seedling black walnut. The tap-root of such a plant should be cut off at *a*, and the larger lateral roots reaching below this point either spread out or shortened at planting.

The main object in shortening the tap-root is to force outside or lateral roots the following season, but it also renders transplanting less troublesome, as it would be very inconvenient to dig trenches or

holes three feet deep in which to set seedlings not more than one or two years old. These tap-roots are doubtless of value to trees growing thickly in the natural unbroken soil of a forest, and where there is little room for side or lateral roots to grow, without coming in contact with those of neighboring trees. Where it is necessary for roots to go deep to find moisture, as when growing on high and dry soils, it is seldom that trees growing sparsely or in low moist soils retain their tap-roots many years, if they have them at all. Therefore they can only be considered necessary appendages under certain conditions, none of which often exist in cultivated trees. I am well aware, that there are arboriculturists in this country who will not agree with me in this, for some often claim that the central or tap-root is a very

Fig. 2.—SEEDLING BLACK WALNUT.

essential part of a tree, and for this reason they advocate planting seeds where the tree is to grow, in order that it may be preserved intact. But with all due deference to the opinion of these gentlemen, my long experience with trees has shown me that tap-roots are but short-lived at best, except in rare instances, and only with trees growing on dry, hard soils, where all the roots go down deeply in order to reach moisture. I have taken up thousands of trees from moist soils and of all ages, from one to twenty or more years old, and I never found one with a tap-root of any considera-

ble size, and generally there was none at all on trees after they had reached the age of a half dozen years or more. I have also seen hundreds of acres of our largest forest trees turned out by the roots by tornadoes, and by stump-pullers in clearing the land for canals and railroads, but not one in a hundred of such trees had anything like a tap-root.

The Disease in Western Cattle.

There has of late been much excitement among the cattle men of Kansas and elsewhere at the West, as to the nature of the disease that has appeared among the herds. Some have asserted that it was the dreaded foot-and-mouth disease, and that the most stringent quarantine was needed to prevent its spread. Others have denied that there was any cause for alarm, but that the deaths were due to the poor condition of the animals at the end of a hard winter. A recent gathering of Western veterinarians claim to have discovered that the cause of the loss of hoofs and other alarming symptoms is due to ergot. It is well known that the continued use of ergotized rye produces most serious results in man as well as in domestic animals. It is not generally known that the seeds of various grasses, as well as those of cultivated grains, sometimes become ergotized, and when in that condition, are poisonous to cattle. A large share of the wild hay cut on the Western plains is of species related to the cultivated rye, and is often called "Wild Rye." An examination of the hay upon which the diseased animals have been fed, shows it to be infested with ergot to an extraordinary extent. As the manifestations of the disease, the loss of hoofs, etc., are similar to those caused by ergot poisoning, the veterinary gentlemen feel warranted in declaring that there is no dangerous contagious disease, and that the unwholesome fodder is sufficient to account for all the alarming symptoms.

Bogus Butter.

The testimony taken by a Committee of the State Senate, has opened the eyes of the housekeepers of New York City to the character of much of the stuff sold as butter. The methods of making oleomargarine, butterine, and other compounds, known collectively as "Bogus Butter," as described by the workmen employed in the factories, are not such as would tempt one to prefer them to butter. The law as it has heretofore stood, tolerates the making of these substitutes, but requires that they shall be distinctly labelled, and sold for what they are. A most excellent provision, but the testimony before the Committee showed that this law does not enforce itself, is universally disregarded, and that these compounds are openly sold, and at high prices—for, what they are not—butter. Our position with regard to these butter substitutes has from the first been this: It is not a question whether they taste as well as butter, or whether they are as healthful as butter, but that not being butter, a well-known product prepared in a definite manner, no one has a right to substitute them for, and sell them as butter. It is a falsification, and should not only not be tolerated, but both the buyer of butter and the maker of it should be protected against this fraud. If beef and horse-tallow may be sold as butter, then horse and mule-flesh may on the same grounds be sold as beef and veal. Unless methods can be devised by which these butter substitutes can be sold for just what they are, then the law should prohibit their sale altogether. The loss to the dairy interests of New York State is already estimated to be upwards of five millions of dollars annually. What may be the loss in health to those who purchase these stuffs as butter can not be estimated. Absolute honesty and integrity in our food supplies should be insisted upon, and the sale of false milk, false butter, false sugar, flour, etc., be prohibited by severe penalties. Giving a stone instead of bread is condemned by high authority.

A Medium-Sized Barn.

H. H. HARRIS, ME.

The best site for building the barn shown in figures 1 to 6 is on a side hill. The cellar (fig. 4), eight feet high in the clear, is divided into root cellar,

Fig. 1.—SIDE ELEVATION OF BARN.

boiler and feed room, and manure cellar with pig pens. The brick wall between the root cellar and manure cellar is two bricks thick and three feet high, with a two-inch plank eight inches wide on top. The studding, three by five, is set on top under the cross sill of basement and boarded on both sides. The wall between root cellar and boiler room is one brick thick and two feet high, with studding and boarding the same as the other

etc. The passages between rows of cattle stalls are closed by gates, which can be swung back out of the way. The top part of the barn doors are fitted with sash as shown in figure 1. The wagon room has sliding doors with double tracks so the half-doors can run past each other; doors to

The Best Prices for the Best Fruit.

One who visits the markets will observe that a slight difference in quality of fruits is accompanied by a large difference in price. Take peaches, for example; dealers know that however the market

Fig. 3.—CROSS-SECTION OF FRAMING.

harness closet are arranged the same. Height of basement, nine feet in the clear. The main floor (fig. 6), contains drive floor, *a*; hay bay, *b*; shop, *c*; carriage room, *d*; meal room, *e*; pen for absorbents, *f*; (dry earth, muck or sawdust) and tool room, *g*. The carriage room has double doors and tracks. The meal room has bins with hopper bottoms and spouts to basement as shown by dotted lines. The ventilator trunks extend up from the floor, and are made with doors on rear sides at different heights for throwing bay through to the basement. The floors are double, one-inch boards (basement the same), with the exception of drive floor, which is one-inch under floor and two-inch plank on top. The stall floors in basement are two-inch plank on double one-inch floor; scaffold floor double boards. The cross section (figure 3) shows very plainly the manner of framing, form of truss, position of truss rods, bolts, etc.

Estimates of Material and Labor for Barn.

walls. The door in the west end is made in three parts; the two bottom doors swing as shown by the dotted lines. The upper door is four feet high, with sash, and hung to turn up, having a balance weight and cord. The cellar contains a large manure pit, *a*; a root cellar, *b*; pig pens, *c*, *c*, and boiler and feed room, *d*. The boiler is shown at *e*. The basement (figure 5) is forty-eight

Fig. 4.—THE CELLAR.

by ninety-six feet, and contains a stable, *a*, for three horses; stalls for forty-three head of cattle, *b*, *b*; sheep pen, *c*; four loose boxes for cows or calves, *d*, *d*; wagon room, *e*; feed floors, *f*, *f*; harness closet, *g*,

The above medium-sized barn is well suited to the needs of the average farm upon which all kinds of live stock are kept. The cost of construction will vary somewhat in different localities.

Fig. 5.—THE BASEMENT.

the fruit. Within a few years, peach orchards have been largely planted in localities not before regarded as favorable for peach-culture, and the increased competition thus caused, will tend to reduce the price of common fruit. Those will be wise who strive not to send the greatest number of baskets or crates to market, but to send the best fruit. The time to prepare for this is soon after the blossoms have fallen and the "set" is seen. All who have practised thinning peaches, are sure that it is profitable. While the fruit is less in numbers, there are as many baskets. If two-thirds of the fruit is removed at the first thinning, the remaining third will usually be an excessive crop, and require a final thinning as the time of ripening approaches. We speak especially of peaches, as the results of thinning are more strikingly seen with these, and they have a great tendency to overbearing, but it will also be found profitable with choice pears, especially those which

Fig. 6.—THE MAIN FLOOR.

tend to form clusters. The culture of choice early apples is strangely overlooked; they are the most profitable of all apples within easy reach of a market, and judicious thinning is amply repaid.

How to Make and Set Lightning Rods.

The extra charge of electricity in the passing cloud wants to get to the earth, and it will effect a passage if it is possible. The air resists it. If there is just enough of even a poor conductor to enable it to overcome the air's resistance, down it will go. 1st. If the partial conductor can not carry it all, it will find a way, splitting trees, demolishing house-timbers, numbing or destroying living bodies.—2d. It will choose the path that offers the least resistance. It will follow a long way round through copper or iron, rather than take a short cut through any poorer conductor.—3d. If a sharp point is at the top of a roadway, it will come down in a small stream; but if a large ball or blunt end is presented, it will come down in a mass.—4th. It will seek the shortest possible route through the resisting air.—5th. If a rod of iron stands on one end of a roof, and an electric cloud chances to pass near the other end, and there is some moisture or metal in the building, there may be on the whole a better roadway from the cloud to the earth, than to go through the long air space to reach the rod, and that part of the barn may get the charge.—6th. If in passing through a building, the electricity has to cross an air space, near hay or straw, it may develop heat in the air and it will be quite likely to start a fire.

HOW TO SET LIGHTNING RODS.—There is a great deal of nonsense and humbuggery about Lightning Rods. All that is needed is to furnish the electricity with a better channel than it can find in a barn or house, or other building. Run a round or square iron rod, three-quarters to one inch through, or a copper one, five-eighths inch in diameter, down in the earth where it is always moist and up on the outside of the building, to a few feet above its highest point, and the electricity will always follow that rod. If the top of the rod terminates in one or two, or better three sharp points, kept bright by silvering or nickeling (not absolutely necessary), the electricity will come down so quickly, that it will never be perceived. A galvanized iron rod (that is one coated with tin or zinc) will last longer, because it will not rust.

NOTE 1.—The conducting power of a lightning rod seems to depend largely upon its surface; hence, a gas pipe does nearly as well as a solid iron rod.

NOTE 2.—The twisting of rods, the many ingenious forms so much set forth, and plating, are needless expense. Give the electricity a good sized metal rod with no breaks, and it will not care for twists and grooves and angles.

NOTE 3.—Glass insulators, angles, braces, etc., are an useless expense. If a rod is held upright by wooden supports, the lightning will never leave the metal to go off through wood of any kind.

NOTE 4.—Let the top end of the rod be above the highest point of the roof, chimney, or cupola. If the roof is large and long, run the rod up to the ridge and along it, with a branch running up in two or more places. It is well to have the upright rods and points so high, and frequent, that there will be no points of the roof more than twice the height of the rod from its foot, thus:

Let A and B be the ridge of a roof, with an iron rod running along it and down to the moist earth; E and F two upright rods, with one or more sharp points at the top, and welded fast to the running rods A—B. If the distance A to C, or C to G, or G to D, or D to B, be not more than double the height of the rods E and F, they will afford ample protection to the roof.

MAKE YOUR OWN LIGHTNING RODS.—Buy enough inch iron rod, round or square (it is cheap now). Have one end planted in the earth some ways into soil always moist, with any larger old iron of any kind in contact with it. An old iron mould-board will do; or let its foot stand in a well that is never dry. The rod may connect with an ever-flowing tile or stone drain. Run the rod up the outside of the building, wherever most convenient, either at the gable end, or by the side over the eaves, and along the roof to the ridge and along it. Support the rod where needed with wooden blocks or braces, or brackets, nailed against the side of the house. Have no break in the rod anywhere; if in pieces, let the blacksmith make a good weld, not letting the welded part be smaller than the rest. Get your blacksmith to weld on some half or three-quarter inch rods as needed, according to Note 4 above. Let him split the top end into three parts, flaring them out three ways, or weld on three small pieces four or five inches long, sharpening the point. The tips you can have covered with a little gold or silver leaf, or if convenient, have them nickel-plated. If not easy to do this, apply a little paint, and wrap the points in gold or

silver leaf, or in tin foil.—All the above will cost but little, and will be just as effective as the five or ten times more expensive lightning rod man's "jiggle-ma-gees."

N. B.—Many dealers supply ready prepared three-pronged plated points at small cost, ready for you to screw them on to the top of the upright terminal rods. Lightning rods induce a feeling of safety.

Animal Ailments.

DR. D. D. SLADE.

CRIB-BITING.—"Is there any way of preventing a young colt from crib-biting?"—Turn him out into a yard or enclosure where he can get exercise and a chance to pick up earth. If obliged to house him, put him into a loose box where there is no woodwork which he can seize with his teeth. Give him exercise in some way.

IMPACTION OF THE MANIFOLDS.—"Is there any remedy where the manifolds become packed so hard that it will require some effort to move them, which condition was shown on examination?"—"If the diagnosis of this condition can be made from the symptoms, and such is generally the case, a full cathartic should be given without delay, consisting of a pound of Epsom salts to the ox or cow, to which may be added two ounces each of gentian and ginger, and twenty drops of croton oil. Stimulants must also be given, of which carbonate of ammonia in four-drachm doses every four hours is perhaps the most suitable. The action of the purgative may be hastened by injecting warm water into the rectum. The animal should be encouraged to drink all the fluid possible. If in twelve hours there is no action of the purgative, it may be repeated.

RETAINED AFTER-BIRTH.—"Can anything be done for cows that do not clean?"—"There is too often anxiety on this point, when, with a little patience, nature will complete what she has begun. If there is delay beyond forty-eight hours, the placenta, or after-birth, with the membranes, should be removed by mechanical means. The hand, well covered with oil or fresh lard, should be carefully passed into the vagina, and, following the cord, which is kept tense with the other hand, the placenta is grasped, and if retained by centers of attachment, these are to be gently peeled off or squeezed by the fingers, and the whole mass removed. All should be accomplished with the utmost gentleness and care. A dose of Epsom salts may sometimes be useful in hastening matters, if the above method is not practicable.

CLIPPING HORSES.—"There is no subject upon which there is a greater variety of opinion than this. It would be impossible to give an opinion suitable to every case, but the following will apply generally. Nothing can compare in beauty to the natural coat, when in its best condition. Where speed is required and the coat is very long, clipping may be done, provided care is taken afterwards to prevent chills. The operation should be done in early winter. The animal should never be allowed to stand exposed for any length of time to cold winds—pneumonia and congestion are the frequent consequence. At best, it is an unnatural proceeding, and is too often a substitute for elbow grease, and is always attended with risks. Sheep are often killed by cold storms after shearing.

SCABBY SKIN DISEASE.—Manifested by sores in the mane and top of shoulder. Give more laxative food, roots, and bran mashes, and moderate exercise daily. Keep the skin clean by thorough grooming, brushing and rubbing. Use upon the sores daily a small amount of iodine of sulphur ointment.

BLACK LEG IN CATTLE.—Black leg is a constitutional malignant affection, scientifically known as Anthrax, or Charbon, and communicated by a virus or poison. The exact conditions under which the disease arises are at present unknown, but scientific research has established the fact that it is due to germs which are developed under certain atmospheric conditions upon lands which are rich and undrained. There is no cure adapted to all cases. The diseased animals must be at once separated from the healthy, and kept under strict guard. All carcasses and everything which has come in contact with the disease, must be burned or buried very deeply. All infected buildings must be thoroughly disinfected, and pastures abandoned. Stamp out the disease if possible.

ITCHING CATTLE.—In all probability the irritation is due to the presence of parasites, if not to lice, to an insect which burrows beneath the skin, and thus escapes superficial observation. If due to the first cause, bathe the parts thoroughly every day, with a saturated solution of kerosene and water. If to the second, use sulphur ointment rubbed into the parts, especially where there are pimples or excoriations. Keep the animals clean by the thorough use of a card and brush that are kept for them alone, and for no others. Keep the premises clean.

DIARRHŒA IN CALVES.—This is due to imperfect digestion. Change the food and give half the quantity of liquid. Scald the milk, adding sufficient flour to thicken it. If this does not relieve, add a little prepared chalk to the food. Keep the animal clean and dry in a warm, sunny pen. Feed with regularity three times a day.

COAL-ASHES TO SWINE.—Coal-ashes are not injurious, although wood-ashes are preferable, and swine should have access to them. Black teetb will not kill the animals, if proper treatment is adopted. Let them have access to earth, charcoal and wood-ashes. Keep the skin clean, and allow plenty of pure air and water, and when possible, green food. If necessary, give half an ounce of sulphur with the food, according to circumstances.

PARASITES IN NASAL PASSAGES.—These are the larvae of a fly which creep up into the nose of sheep. Boil one pound of tobacco in a gallon of water, turn the sheep on to its back, and holding the head firmly, inject with considerable force by means of a good syringe, a table-spoonful of the liquid, directing the syringe upwards, into the nostrils. Repeat the operation from time to time, as long as there are symptoms of the presence of parasites.

FEEDING OF HORSES.—The fattening qualities of corn as compared with oats, is shown by the greater amount of oil it contains, being nearly double that of oats. Therefore, if used as food for working horses, it should be given in these proportions. Equal quantities of corn and oats should not be ground together. Such a mixture is dangerous. Oats should be given whole, unless necessary to bruise them for a special reason. Corn ground with the cob adds to its bulk, and does away with some objections to its use. Hay fed with the grain, helps the digestion of the latter. We should prefer not to moisten the grain—particularly if the animal is a greedy feeder. Bran mashes should be given at least once a week in place of grain, or better still, carrots twice a week.

GARGET.—ROPY MILK.—Several correspondents desire information in regard to garget in its different stages. This disease is an inflammation of the milk glands, most commonly coming on just previous to or at the time of calving, but may appear with greater or less severity at any time when the flow of milk is abundant. The symptoms are, enlargement of the udder, which becomes hard, congested and painful; one or both sides may be attacked, and, on pressure, hard cakes may be felt in the udder, the teats sympathetically becoming tense, painful, and often nearly or entirely impervious. The milk, when drawn, is ropy, and if the inflammation goes on, may become bloody and mixed with matter. Of course, the object of any treatment is, first to allay the inflammation. For this purpose, bathe or foment the udder and teats in warm water, or with warm soap suds. If the organ is very much swollen, support it by means of a bag or bandage passed over the hind-quarters, cutting holes for the teats. In this bag may be placed a linseed-and-meal poultice, if the inflammation continues great. If necessary, draw off the milk by a milk-tube, which should be done three times a day. Give a purge of half a pound of salts, lessen the amount of food, which should be very simple, without grain, and offer very little fluid. If the glands remain hard after inflammation has subsided, rub with iodine ointment. The too early and sudden removal of the calf often brings on this condition. The restoration of the calf may sometimes greatly accelerate the cure. If we interfere with nature's laws, we must sooner or later suffer the consequences.

Commencement of the American Veterinary College.

—This institution is gaining by degrees the position it has a claim to by the good work it is doing—and the progress and recognitions that our people are beginning to grant to Veterinary Medicine. But a few years ago Veterinary Colleges were unknown in the United States, and now that several have been open, have died and been resuscitated, the American Veterinary College, with her Graduating Class of '84, her alumni of one hundred and twenty-three graduates, stands ahead of all institutions of its kind in this country. The winter session has just closed, and the following gentlemen have received their degree: Francis Sherwin Allen, B. S., of Mass.; Armin Ernest Bram, D. V. S., of N. Y.; Arthur Decalb Galbraith, of Indiana; Elwood G. Gilbert, of Pa.; Wm. Henry Gribble, D. V. S., John Hamlin, D. V. S., Arthur Hudson, Helme, Walter George Hollingworth, Isaac Newton Krowl, of N. Y.; Morton Edward Knowles, of Indiana; Eldon Leon Loblein, of West Indies; Martin John Otto, of Mass.; Matthew Alexander Pierce, of N. J.; Edward Canfield Ross, of Conn.; John Elmer Ryder, of N. Y.; Orrin William Snyder, of Ill.; Thomas William Spranklin, of Md.; Richard Augustus Stoute, D. V. S., of West Indies; Nicholas Pierce Valerius, of Wis.; Andrew Goodyear Vogt, of N. J.; Hamilton Vreeland, of N. J.; Thomas Eldér White, of Mo.

Chat with Readers.

Sweet Potatoes in Massachusetts.—*T. Volk, Fall River, Mass.* The variety generally cultivated at the North is the Nansemond. All the New York seedsmen keep the sets at the proper season for planting, which is in May and June.

Water Cress.—*G. Hall, Berkley, Mass.*, thinks he has just the place for water cresses, and asks if he can find a ready market should he grow them. In large cities there is a ready sale. As the crop can only be grown in localities that are watered, the supply can not be increased indefinitely. The New York market is never over-stocked, and they generally bring paying prices.

Pop Corn.—*S. Rowe, Washington, Kans.* We have no statistics as to the yield of pop corn per acre. There are several varieties and they differ greatly in the size of the ears. The varieties most used are the Shaker and the Rice, the former is a favorite with those who pop it for sale. The Dwarf Golden is a curiosity on account of its small size, and it pops well, but is too small to be profitable.

Pruning an Arbor Vitæ Hedge.—*L. N. Cook, Salem, N. C.* The hedge may be pruned for two purposes; one, to promote a stronger growth, and the other to diminish the vigor of the trees. For the first purpose, prune in autumn, after the summer's wood has ripened, usually in October. To weaken the growth, and keep the tree within bounds as a hedge, prune before the new wood is ripe, in June.

Vine to Cover a Building.—*G. Smith, Norfolk, Conn.*, wishes to cover a building, and asks if there is any evergreen that will endure the winters in his rather bleak locality. If not, what grape-vine would be best. There is no evergreen vine that can be depended on for such a place. If the grape vine is to be used without reference to its fruit, the Clinton is one of the most suitable. Indeed the fruit of this, if allowed to mature thoroughly, is very acceptable. The Concord would be hardy enough, but its leaves are not so pleasing as those of the Clinton.

Why Blanch Celery?—*A. M. Smith, Manistee, Mich.*, asks us: "Why is it necessary to blanch celery, why not eat the stalks green?"—If our correspondent will make one trial—even a single bite—of a green stalk, and one that has been properly blanched, the question will be answered. The absence of the green color is of no consequence in itself, but it indicates that the light has been excluded, that the stalks have become crisp and brittle, with few strong fibres, and especially that they have lost their strong bitterish taste, which is so disagreeable that no one would eat celery if it remained, leaving just a trace that gives a pleasant flavor, liked by most persons.

Hog Cholera.—*J. W. P. King, Shannock Mills, R. I.*—It is so improbable that the disease known as "Hog Cholera" in the Western States, can have appeared among your swine, that you should first consult a veterinary surgeon, and ascertain what is really the trouble, before you seek a remedy. The best authorities regard the so-called Western hog cholera as due to a low condition of the system, resulting from impure water, exposure, and poor food. The conditions of swine-keeping in New England are rarely such as will produce this low condition among the animals, and the safest course will be to ascertain what the trouble really is, before attempting to treat it.

How he Managed his Potatoes.—*Mr. G. Q. Cook, Red Lake Falls, Polk Co., Minn.*, adds his experience to the methods we have already given for forwarding early potatoes. As this may still be useful in some far-Northern localities, we give it. The seed potatoes were selected as nearly of a size as possible, set on end in boxes or crates, in a warm and sunny place. When good healthy shoots, from half an inch to an inch long had grown, the potatoes were so cut as to leave a piece to each shoot. These pieces were dropped every nine inches in rows three feet apart and kept well cultivated. The varieties, Early Rose and Peerless, yielded three hundred and four bushels to the acre—good farming or gardening—which ever it may be called.

Rescue Grass.—*G. M. D. Patterson, Robertson Co., Texas.* The grass about which you inquire was introduced about twenty years ago in France, with a great flourish under the name of "Schrader's Bromus" (*Brome de Schrader*). It was predicted that it would completely revolutionize agriculture and it received considerable attention for a time. Of late years we have heard nothing of it. The French catalogues of the present time state that though it has been overpraised it may be useful "in certain countries and in various circumstances." None of the species of Bromus are of agricultural value. You would probably find the "Johnson grass" (*Sorghum halepense*), a perennial, much more useful in your locality.

Girdled Fruit Trees.—*Mr. N. Prefontaine, Beloit, P. Q.*—We gave the best methods for saving girdled fruit trees in the *American Agriculturist* for December last (1883). Where the girdling is not complete, the tree may live after the wound is covered with waxed cloth. A mixture of clay and cow manure may be applied to prevent evaporation. If the inner bark is gnawed off all the way round the wound must be bridged, which may be done with three or more cions cut from the same tree, or one of the same kind. The ends of the cions are cut slanting and placed under the bark above and below the wound. These are "double" cions, as both ends unite with the stock and furnish a passage for sap from the roots to the leaves. If the wound is near the base, it may be covered with a mound of earth, otherwise apply one of the coverings given above.

Carp and Ducks.—*John H. Doughty, Woodbury, Queens Co., N. Y.*—Has heard that German carp would destroy young ducklings and goslings by pulling them down beneath the surface of the water and drowning them. As one of the prominent claims in favor of carp-culture is, that this fish is an exclusively vegetable feeder, it is hardly possible that it should destroy young water-fowls "just for the fun of it." As mud turtles have been detected destroying young ducks, etc., and it is alleged that bull-frogs will prey upon them, it is most probable that the disappearance of aquatic fowls is due rather to one or the other of these amphibians than to the quiet, well-behaved vegetable carp, which is represented as having no faults.

The Legal Weight of a Bushel of Parsnips.—*M. Ettisberger, Burlington, Iowa.*—The weight of a bushel of the different kinds of farm produce is fixed by the Legislatures of the various States and Territories. There is no general law, and as a consequence, there is little uniformity in the weights. While some States fix the weight for nearly everything sold by the bushel, others give them for only a few leading articles. Parsnips, for example, have received attention in only four States, and in Canada. While forty-five pounds of parsnips pass for a bushel in Connecticut, the farmer in New Hampshire and Ohio must give sixty pounds, while Rhode Island lets him off with fifty pounds, Canada has sixty pounds. Beyond these few States, none of the others, up to a few years ago, legislated on the parsnip.

Parasites on Animals.—*C. Todd, Plymouth, Iowa*, writes that he has successfully destroyed lice upon various animals by the use of the seeds of the Perennial Larkspur (*Delphinium formosum*); the seeds are steeped in water and the infusion applied with a brush. He says that he finds this more effective than any other remedy he has tried for lice upon farm animals, and those of the genus *homo*. He suggests that farmers should procure seeds from the seedsmen, sow a small patch and raise the seed for use. While the infusion of the seeds is harmless applied externally, it should be known that it is violently poisonous when swallowed, and care taken to avoid accidents. Stavesacre seeds is a very old remedy for animal parasites. They are the seeds of another Larkspur (*D. Staphisagrum*), and are still sold by some druggists.

Shells for Poultry.—Ground oyster shells is one of the best forms in which lime may be supplied to poultry. A. H. Davis, Mitchell, Ind., finding that oyster shells would be very expensive, asks if the shells of the fresh-water mussels, or clams, as they are sometimes called, may not be used as a substitute. These mussels are very abundant in the western streams, and may be had for the expense of carting. Shells of all mollusks are essentially alike in composition, consisting of carbonate of lime, mixed with a small amount of animal matter. Some of the fresh-water shells contain very little lime and are very fragile; others are nearly as hard and firm as an oyster shell. Have any poultry-keepers tried pounding up the whole, the contained animal as well as the shell? Let us have experience with fresh-water mussels or clams as chicken feed.

About Peanuts.—The *Rev. John Otten, Morrilton, Ark.*, writes that the soil in his section is well suited to peanut culture, but is in doubt whether the demand is sufficient to warrant raising them on a large scale. In this country peanuts are used for eating, when roasted, and by confectioners for making "peanut candy." In France they are used for pressing to obtain their oil, for which purpose they are imported into Marseilles, from Africa, by the shipload. We have not heard of their being pressed for their oil in this country. Cotton seed yields such an abundance of oil and is so cheap that it will not pay to cultivate a plant especially as a source of oil. The only use for peanuts, that we have heard of, aside from those mentioned above, is for the adulteration of chocolate, for which they are said to be well adapted. The demand for eating is so large that the crop is regarded as a profitable one on land suited to it.

About Staking Trees.—*J. J. Corrigan, Factoryville, Pa.*, asks us if in transplanting fruit or ornamental trees, it is best to set two stakes two by five inches, six inches apart, and then to nail strips connecting these stakes, in such a manner as to exclude all sunlight from the trunks, in order to protect the tree from cattle and sheep. Our correspondent finds nothing on this point in Barry's and other works, and comes to us for advice. Barry and other writers upon fruit culture, suppose that a community settled long enough to have fruit and other trees will provide for shutting up their animals, rather than make every owner of a tree fence it in from injury by cattle and sheep. A few local laws, well enforced, or a few prosecutions of those who allow their animals to run at large and injure the property of others, are what are needed. Trees often require stakes to protect them from injury by winds, never against cattle and sheep.

Asphalt or Pitch Walks.—*A. C. Tillotson, Northport, N. Y.* A number of the compositions for making garden walks are covered by patents. A simple mixture of coal tar and sand will finally become hard, but it requires a long time. The best home-made walk we have seen was made as follows: The bed of the path was excavated to the depth of three inches and provided with edgings of bricks, laid on end or with board edgings. Coal (or gas) tar, three parts, and common pitch, one part, were melted together and boiled for half an hour. This composition was mixed on a board platform with dry sand, just as mortar is mixed, and of a similar consistency and the mixture spread upon the path. Boards were laid upon the surface and pounded, to level it. Dry sand was then sprinkled over the surface, which was then rolled. The walk in a few days became as hard as one of stone. It is troublesome to make such a walk.

Sawdust as Bedding and Manure.—*Geo. G. McGrail, Winona, Ohio*, asks if sawdust that has been used as bedding in stables, and mixed with the manure in the heap, can produce, when applied to the land, any deleterious effects. Shaping his question in another form, he asks: "Does either chemistry or experience show that it is not well to make use of sawdust in our stables?" There is nothing, so far as we are aware, in the teachings of chemistry, or in the practice of our best farmers, to show why sawdust should not be used in stables, or why the material, which readily ferments, should not be employed as a fertilizer. Sawdust fresh from the mill, has been sometimes used as a mulch in nurseries and fruit gardens, and has been charged that in this condition, it bred an injurious fungus. This charge is not well substantiated, and such sawdust is very unlike that which has been soaked in liquid manure.

How Can Oleomargarine and Butterine, etc., be Detected?—*John Reese, Covington, Ky.*—While the detection of these substitutes for butter is not difficult to the skilled chemist, unfortunately no method has yet been devised by which the consumer can readily know whether or not he is defrauded. Those who purchase butter for retailing, know what they are buying. Until we have laws to properly protect the consumer, his only safe course is to purchase of men who would no more sell him vile grease for butter, than they would adulterated bread to eat it upon. Moralists will do well to consider what will be the effect upon a community where the people begin the day with a breakfast at which they butter their bread with vile fats, have "bob-veal" for their cutlets, and drink an infusion of peas, parched ship-bread, or rye, thinking it is coffee. To bring up a horse or a cow to future usefulness, we must give the best and most honest food. What sort of men and women will result from a daily food of bogus stuff?

An Evergreen Blackberry.—*Ira B. Sturges, Portland, Oregon*, asks for information about what is known upon the North-west coast as the "Evergreen Blackberry." There are but a few vines in cultivation near Portland, but he thinks they will be valuable to grow for canning. They begin to ripen after all other varieties are out of the market, very prolific, and when frost comes, they are loaded with green and ripe fruit and blossoms. Mr. S. can learn nothing about them from the books and catalogues, and comes to us for help. From the lateness of bearing and from the remark that the vines require the support of a trellis, we have little doubt that this will prove to be a form of the common blackberry of Northern Europe, *Rubus fruticosus*. This, in England, is almost evergreen, and is so variable that over twenty wild varieties are recognized by English botanists. One of the varieties has long been cultivated in this country as the "Cut-leaved" and "Parsley-leaved" Blackberry. Its fruit is large and abundant, but one who has had the Kitatinny as his standard of quality, will hardly class this as among the best. Still it may improve in the genial climate of Oregon. We suspect that this is the direction in which Mr. Sturges must look for the origin of his Evergreen variety.

A Trouble with a Cherry Tree.—*W. C. Gomerod*, who lives just outside of the City of New York, has a single cherry tree with a wide spread head, and annually bears an abundance of fruit. The cherries are white on one side, and red on the other, but he has never known a single cherry reach maturity, or even approach it, without being unfitted for use by a worm. Mr. G. has tried wood-ashes, sulphur, and lime upon the root, and has also driven many large nails into the base of the trunk of the tree, all without effect, and asks us what he shall do. Had he applied the ashes, etc., at the flag-staff on the Battery, or driven the nails into the lower part of that pole, they would have been just as effective as to have applied them to the cherry tree. If a worm is found in the fruit, it came from an egg laid on or in the fruit. As soon as the blossoms begin to fall this spring, watch for the insects that may be at work upon the young fruit, catch them if possible, and send specimens of them to us. If no insects are found, send us some of the cherries (in a box so they may not be crushed), and well advanced toward maturity. Is this trouble confined to this particular variety of cherry? How about other trees in the vicinity, are they free? If there are no other trees near by, set out several, as they cost but little, and try to ascertain if it is a general trouble, or confined to a single sort. Manure applied to the tree will be far better than nails.

Castor Oil Beans.—Each spring there are numerous inquiries as to the culture of Castor Oil Beans. *T. D. Smith*, of Knotwell, Phelps Co., Mo., leads the list this season, and we answer those who will follow through him. The uses of castor oil are limited, and it would be very easy to overstock the market. Hence, several years ago, the few pressers who had put up machinery for preparing the oil, took care to keep the business in their own hands. They furnished the seed to farmers, gave instructions for cultivation, and contracted to take the crop at a stated price. So far as we are aware, the same conditions prevail, and outsiders who raise a crop of beans, find no sale for them. There is no difficulty in raising the beans on any good corn land. The ground being well plowed and manured, is laid out in rows six feet apart, and between every sixth and seventh row sufficient space is left for a wagon to pass in collecting the crop. Two or three beans, previously soaked over-night in hot water, are planted every four or five inches in the row, and these in cultivation are thinned to one foot after the plants are six inches high. Good cultivation is given all through the season, and when some of the pods on a cluster crack open, the clusters are cut, taken on a wagon or sled to the "popping yard," where the beans are thrown out by the explosion of the pods. Twenty bushels to the acre is a fair average crop, but some lands yield more.

Dogs and Dog-Shows.

We believe in Dog-Shows, because they encourage the purer breeding and development of a class of

animals which God intended should be most serviceable to the human race, especially to farmers. So far from being classed as curs, worthy of general extermination, dogs should be regarded and treated as farm helpers, capable of valuable service as watchers, destroyers of vermin, tenders of flocks, etc., etc. That they are not generally more useful, is the fault of the owners. If steps can be reckoned as money, the dog may be made to save these by all who have to do with cattle and sheep, which in any considerable numbers are very difficult to move and care for without his help. A moderately large-sized dog may be made to do the churning of a dairy of several cows, and serve as a motive power for small machines.

It is now eight years since the dog shows were inaugurated in this country by the exhibition here in New York. The annual displays here have been uniformly successful, and the number of animals competing for prizes during this year's (1884) show evinces no abatement in interest. Our artist reproduces some of the types of dogs seen at the various displays. The tastes and preferences of the surging throng of visitors are plainly indicated by the departments and sections best patronized.

most fitting trio in field sports. The departments for the Spaniels, Beagles, Retrievers, etc., have their admirers, while those whose tastes incline them to "ride to hounds," find numerous animals suited to their fancy. Ladies, and others, who mainly regard dogs as pets and companions, gather in the departments assigned to what are called "Toy dogs." Here blanketed and shivering Italian Greyhounds with their pipe-stem legs, stupid

Poodles, Pugs, of beautiful ugliness, and, various Toy Spaniels and Terriers make up the kennels. The breeds of use on the farm attract no little attention in these shows. As a dog of general util-

St. Bernard, though the true breed is rare and costly, is about his equal, and a most useful dog

for every purpose save for breeding, may be found in a high grade in either of these breeds. As useful farm animals, the various breeds of shepherd dogs take a high rank, and none are superior to the

Scotch Collie. Vastly more intelligent than some two-legged animals, he can be very serviceable at whatever work may be required of him, and is withal devoted to his master. Bull dogs and Spitz dogs are treacherous, especially when old, and sometimes needlessly savage to strangers. They have many useful traits, but these are more than offset by their uncertainty of temper. In selecting a farm dog, weight and strength are important points. If these are united to fair intelligence, and a gentle disposition, it makes little difference which breed is chosen. But there are dogs and curs, and pure-bred dogs that have to bear the sins of all these mongrel whelps. A dog may be valuable if not pure-bred; if it be a cross between two pure dogs, it may unite the good points of both. But

Engraved for the American Agriculturist.

ity, excellent enough to watch, and intelligent enough to learn whatever tasks he may be required for, and sufficiently heavy to do mechanical work, the Mastiff has no superior. The closely related

the mongrels, with which the country is filled, and which cannot be traced to either parent, should have no place upon a farm—or elsewhere. The farm dog, to be helpful, should have duties to per-

Pointers and Setters attract mainly young men, with a number of older persons known as sportsmen, who evidently count upon a day or two of shooting as the first of human pleasures, and "man, dog, and gun" as a

form and possess those qualities which will enable him to do his work well. He should be kind to children and live stock, and above all be strictly obedient to his master. Much depends upon the manner a dog is trained.

Seth Green and Robert B. Roosevelt Go A-fishing.

ROBERT BARNWELL ROOSEVELT.

On the south side of Long Island stretches a long, narrow lagoon of salt water, fed from the land by innumerable trout brooks pouring their sparkling rivulets, scarcely more than a mile apart; it is connected with the sea by several inlets, cut by the waves through the narrow beach of low sand that separates the bay from the ocean. This lagoon, called the Great South Bay, is in reality sixty miles long, although it passes under several local names, but a boat starting from Rockaway can sail sixty miles eastward without going through any but natural water communications.

The bay formerly abounded with fish. Here weak-fish, king-fish, blue-fish, sheeps-head, sea bass and other species lived and bred, while Spanish mackerel, bonito and various migratory kinds visited it in their season, if they did not deposit their eggs there. They are still fairly numerous, although the fishing has been much reduced by the use of pound nets in and near the inlets, which not only capture fish in immense numbers but of immature size. So Mr. Seth Green, the State Superintendent of Fisheries, and one of the Commissioners, took a yacht and set out on an exploring expedition, determined to investigate the possibilities of the bay. I went along to see that they made no mistakes.

The "Cinderbeds," so called from a peculiar coral formation which grows on them, are the favorite resort of porgies, sea bass and robins or gurnards, while small blue-fish are taken in the channel by what is called "chumming." To the Cinderbeds the good yacht *Au Revoir* flew as fast as the wind and our impatience would carry her. We bought a hundred clams on the way from one of the working boats, with which the bay is dotted every working day in the year, and as soon as we reached our destination east anchor and went to fishing.

Up came the fish by ones, by twos, by threes, at every cast, of all kinds, large and small. The yacht's deck was covered with fish. Fish flopped and sparkled in the sun; fish bounded about the cockpit; fish got under your feet; fish hid away in the cabin. Baskets and boxes were filled with fish, and had it not been for an interruption, the *Au Revoir* would have been loaded down with fish. While these two enthusiastic piscatorial artists were hard at it, with no signs of giving up, a stylish-looking craft sailed by. It had a signal on which was the suggestive figure of a fish, and beneath that the word "Bait," and the Commissioner recognizing it at once as the "chum-boat," shouted out that he wanted a hundred moss-bunkers. Chum is bait, usually moss-bunker, bony-fish or menhaden, three names for the same creature, chopped up fine with a hatchet and thrown overboard from time to time, while the fisherman puts larger and more alluring pieces on his hook. The chum gives out an oil which floats on the water and attracts the blue-fish, while the bait catches them. As the menhaden is oily and nasty to handle it is not a pleasant or a clean style of fishing, but it is the only mode of taking blue-fish which is possible within the bay, where sea-weed usually runs so thickly as to cover a trolling squid faster than it could be got out the length of the line, and often to interfere greatly with the hook while chumming. There is a machine made especially, something on the principle of a patent sausage chopper, to grind up moss-bunkers into minute pieces, but it gets foul if not cleaned carefully, and is not much used except by the owners of boats, that make a business of taking parties out blue-fishing, so that it is called into employment daily.

Probably no two more discordantly harmonious elements could be brought together than the Superintendent and the Commissioner. Each has the firm conviction that what he does not know about fishing is not only not worth knowing but does not exist. They are both so calmly convinced of this fact, and securely set in their ways, that they utterly ignore not alone the suggestions of the outside fishing world, but also of one another. Strange

as it may seem, they are widely at variance, and even though they may be for the first time essaying a style of fishing that they have never tried before, as was the case with Mr. Green in this instance, they are firmly convinced that they know more about it than one who has followed it for a lifetime. So while the Commissioner was satisfied to put on a gut leader that the professionals would have assured him the blue-fish would take off at the first bite, the Superintendent rigged a wonderful gang of small hooks, such as was never seen by the unsophisticated inhabitants of the Great South Bay in their lives before. The chumming having gone on by the boatmen for a short time, the fishing began. Science was too much for the finny tribe and they simply gave up, resistance under the circumstances was a work of supererogation. The odds against them were too overwhelming, and they opened their mouths and swallowed their fate and the hooks together. It was impossible to tell which of the anglers caught the most fish where both were taking them all the time. Bright, shining, gleaming blue-fish came over the stern so fast that they seemed like a long streak of silvery sunlight rather than mere fish. If there were fish galore before, they were more galore now, they were indeed too galore. They were becoming a nuisance, and as there was no evidence that either of the contemplative anglers had the slightest intent of stopping, the only question remaining was how long it would be before the yacht sank under her augmenting load. Fortunately at this point of time dinner was announced, and the alacrity with which they laid down their lines, was only equalled by the enthusiasm with which they had used them, while the amount of dinner they consumed visibly lightened the vessel again. The meal was late, and before it was despatched the tide had turned, and the fish had left, for they rarely bite during more than one tide. So the party devoted themselves to salting down the prey which they had secured, and of which there was more than they could use.

Tall Pea-Vines.—A Substitute for Brush.

While there are very good peas with dwarf vines, all pea-lovers will agree that the perfection of peas is to be found in the Champion of England, and perhaps one or two equally tall growers. While they are so excellent upon the table, they cost a great deal of trouble to produce them, especially in localities where brush is difficult to procure. After trying pea-hurdles and other devices of sticks and strings, we have found no substitute for brush equal to a wire trellis, suggested by one of our correspondents several years ago. This we have since had in use each season, and by proper care in storing it will last for many years to come. The peas are sown in double rows six inches apart. At each end of the double row is placed a stout post, six inches in diameter, which may be round or half-round. This should be placed three feet in the ground, with the soil well rammed around its foot, and be as tall as the variety requires, four to six feet. The wire used is galvanized iron, No. 18, which runs about one hundred and fifty feet to the pound. The trellis is put up by stretching the wire in double strands, separated by the thickness of the end posts. The first or lowest wires are stretched about six inches from the ground, the successive strands at intervals of every eight or ten inches above. Instead of cutting the wire as each two strands are placed, it is well to take a few turns around the post to the place for the next strands, and thus keep the wire all in one piece. The wires, when loaded with vines, will sag, and should be supported every twelve or fifteen feet, by the use of laths or other strips, in which notches are sawed to hold the wires. If the rows are over three hundred feet in length, it will be well to have another post midway, around which a turn is taken with the wire. By stretching the wires as the vines need them, and when the crop is off carefully coiling them and storing the wires with the posts securely under cover for another season, the culture of the tall kinds of peas is greatly simplified.

A Wagon Brake.

The automatic brake illustrated herewith is much quicker made, more simple, just as good—and even better in some respects—than the one described in the February *American Agriculturist*, p. 49. It can be made by any one in fifteen minutes. Take a piece of hard plank an inch and a half or

A WAGON BRAKE.

two inches thick, of the required length; notch one end to fit the axle, and sharpen the other end. Pass a stout leather strap around the axle, nailing each end to the edges of the plank. The end on the ground may be spiked if desired, but it answers very well without it. T. C. R.

Thinning in the Garden.

The novice in gardening matters rarely gives his plants, especially his roots, sufficient room. He can not see why he should sow twenty or more seeds for every plant that comes to perfection. If we were to dibble in a single carrot seed every six inches in a row, it is probable that very few of them would appear as plants. A large number of seeds are sown in order that, by their united effort, in germination, they may break through the soil and allow enough plants to see the light to make a stand. After the plants are up, then comes the thinning, and we cut out with the hoe a large number of heels, parsnips, etc., and finally leave one in a place at intervals of six inches to a foot, according to the variety. Onions seem to do well if left in little clusters to crowd one another, and Joseph Harris says that this is the best treatment for the short kinds of carrots. But these are exceptions, and as a rule the more room roots have, the quicker they will grow and the more tender they will be. Take spinach, for example, though not a root, it needs judicious thinning. The first thinning may leave the plants two or three inches apart in the row; a second time, the plants may be left six inches apart, then every other plant may be taken for use, and the final cutting of well developed plants will be the best of all. Salsify, at best a small root, may be had much larger than we usually see it, and more convenient for the cook, by giving it room. As a rule, our garden crops are too much crowded for the best results.

A Wheel Horse-Hitch.

A method of fastening together the hind and forward wheels of a vehicle to restrain an attached horse, is shown in the accompanying engraving.

A WHEEL HITCH.

It consists of a piece of hard-wood with an iron hook in each end. One hook passes around the felloe of the hind wheel, and the other hooks upon the front wheel. Both wheels are thus kept from turning, and this will be an effective check upon a horse inclined to start off when left standing. The device, as shown above, is small and may be kept in the wagon-box close at hand when needed.

The Fennec or Zerda.

From an examination of its portrait, one would find it very difficult to say what were the relationships of the Fennec. When it was first brought to their notice, naturalists found a similar difficulty in assigning it a place, and it was by some classed

ally they are not cooled down to the danger point until the end of the night, and in most cases the mischief is done within an hour or two of sunrise. When the night is cloudy frost is not feared. The curtain of clouds prevents the heat passing off into space. In a small garden it is not difficult to protect the tomatoes and other tender plants. News-

THE FENNEC OR ZERDA (*Megalotis Brucei*).

with the squirrels and by others with the monkeys, before a study of its teeth indicated that its proper place was among the dogs and wolves. The animal is a native of Egypt and other parts of Northern Africa. It is less than a foot long, with a very bushy tail and a snout much like that of a fox. Its most striking feature is its enormous ears, which are about half as long as the body and remarkably wide. The color of the animal is a pale fawn, or sometimes, a creamy white. The base of the tail where it joins the body, and the tip also, are marked with black. The animal is carnivorous, but is fond of fruits also, especially the date, to reach which it climbs up the lofty trees. It makes shallow burrows in the sand, in which it remains during the day, as it is nocturnal in its habits. The skin of the Fennec is regarded as affording the warmest fur of any in its country. The skins are so small that a garment made of them is very expensive. The scientific name of the Fennec is *Megalotis Brucei*. The generic name of this peculiar animal is from the Greek words for large and ear.

The Destruction by Late Frosts.

Late frost is a constant menace to the cultivator. He has transplanted his tender plants from the hot-beds; his peach trees have their buds just ready to open; his grape-vines are pushing their tender shoots, and in one hour the prospects of a season may be ruined. While late frosts do not bring destruction every year, they come so frequently that it would seem to be worth while to take all possible precautions to prevent injury by them. It does not seem to be generally understood that frost is not something that comes to us from a distance, but is, so to speak, caused by the plant itself. As soon as the plant cools to a certain point frost is deposited from the air surrounding it. Or course this is usually first deposited as moisture, which afterwards freezes. All attempts to avoid injury by frost must be directed towards preventing the plants from cooling. It may encourage those who are disposed to try to shelter their plants, that the protection is required for but a short time and towards morning. The plants begin to cool as soon as deprived of the heat of the sun, and continue to lose heat all night; usu-

ally they are not cooled down to the danger point until the end of the night, and in most cases the mischief is done within an hour or two of sunrise. When the night is cloudy frost is not feared. The curtain of clouds prevents the heat passing off into space. In a small garden it is not difficult to protect the tomatoes and other tender plants. News-

Chickens in the Garden.

The broods hatched the last of April, or early in May, can be safely stationed in the garden, as soon as the vegetables are in sight—the hens being confined in coops close by, with conveniences for food and water. Insects are abundant in a well manured soil, and will be devoured by the chicks with great greediness. They also enjoy the tender weeds, between the rows when they first appear. With cracked corn, insects, and young weeds or grass, they have a perfect diet, and grow very rapidly after warm weather sets in. They are thus an important aid in destroying insect enemies that prey upon vegetables, and the strawberry plants. Squashes, melons, and cucumbers suffer most, and when their leaves appear, a good location for the coop is near these. When chickens get large enough to trouble cultivated plants, they must of course be removed from the vegetable garden.

The European Salamander.

According to the superstitions of the ancients, the Salamander was a creature which could pass through fire unharmed. Indeed, it had an actual fondness for it, and was never so happy as when among hot coals and flames. The animal of which these stories were told, is supposed to be the common salamander of Europe, a little reptile that does not appear as if capable of doing anything remarkable. It is unfortunate in having a fire-proof reputation, for great numbers of the poor creatures have been subjected to trial in order to test the truth of the ancient story, and have miserably perished. The common salamander of Europe (*Salamandra maculosa*) is six or eight inches long, and of the form shown in the engraving. Its color is black, with bright yellow markings and spots. It lives upon land, only visiting the water at the breeding season. Like the toads, frogs, etc., its early life is passed in the water, in the tadpole state. Being nocturnal, salamanders are seldom seen; towards winter they secrete themselves in hollow stumps, under stones, etc., and remain in a dormant state until spring. The salamander produces from glands behind its eyes, and upon its body a thickish, milky fluid which is poisonous to

THE SALAMANDER, (*Salamandra maculosa*).

small animals. This, which is produced in considerable abundance, is supposed to have given origin to the belief that the animal could extinguish fire, and to another superstition, that the animal had the power of surrounding itself with an icy coldness. In this country there are several salamanders and related genera in the Atlantic States, and many more in the new States of the Far-West.

A Lifting Gate.

A gate properly balanced by a weight so that a child even can handle it, is often very convenient, in any circumstances, and especially when snow falls, as there is no shoveling required. Mr. Warren R. Dunston, of Dorset, Va., sends us sketches

Fig. 1.—THE GATE SHUT.

of one easily constructed, and adapted to general use. It may be three, four, or five barred, as desired, and of any convenient width for the use to be made of it. The post, firmly set, extends a little higher than the length of the gate. In front of this and firmly fastened to it at bottom and top, is a board at sufficient distance from the post for the gate to move easily between them. An iron bolt through the large post, and the lower end of the right upright gate bar, serves as a balance for

Fig. 2.—THE GATE OPEN.

the gate to turn on. A strong rope attached to the bottom of the gate, as shown, runs over the pulley and has a weight of iron or stone that nearly balances the gate. The opened gate is shown in fig. 2.

Ayrshire Herd Tests.

The breeders of Ayrshire cattle, at their annual convention last winter, offered fifty dollar prizes for the best milk, butter and cheese tests, made in herds of Ayrshire cows of not less than six, and twenty-five dollar prizes for the best milk and butter tests made by single cows, the tests to continue through the year, and to be made under certain conditions named. The breeders are allowed all the time they need, up to November first, to test their cows and make up their herds before "entering" them. It is greatly to be desired that a number of good herds should compete for these prizes, and that the single-cow milk and butter prizes should also be well contested for. We have great faith in the Ayrshires, and would be glad to have it proved that the breed not only yields milk of the best average quality, which we believe to be true, but that it produces it on a less quantity of food. There is none among all the breeds of cattle usually met with in this country, the milk of which is so easily digested, and which contains the elements of perfect food in such desirable proportions as does that of the Ayrshire. The milk of the Jerseys and Guernseys is richer and less easily digested. That of the Devon is also very rich; the milk of

the Shorthorn and of the Dutch cows is rich in casein (cheese), and is said to be not so digestible. One cause, no doubt, for the superior digestibility of Ayrshire milk, lies in the fact that the butter globules average much smaller in size, than those in the milk of other breeds. This makes the milk a more perfect emulsion, and of a more homogeneous character. The real value of Ayrshire milk is not in its quantity alone, for it is quite likely the Dutch cows—a few of them—will beat the Ayrshires in quantity, but in quantity of milk when compared with the food consumed, and in the quantity compared with the amount of solid food contained in the milk. In these tests this will be shown by the quantity of whole-milk cheese made from the milk of the herd. One of the conditions is that the quantity and character of the food shall be accurately known and certified to. No one will think of restricting the feed of his cows, except to prevent surfeit or damage from over-feeding, for it is a well recognized fact, that great producers are always heavy feeders. A variety of food is of course important, and the character of the food given to the milk cows should certainly be a matter of careful study and experiment.

Should the Ayrshire breeders take hold of this matter with the energy its importance deserves, we may expect a "boom" in Ayrshire stock, as great or greater than that which followed systematic testing for butter among the Jerseys, the results of which are well known. The Dutch, whether called Friesian, or, most absurdly, Holsteins, will have to look to their laurels. There seems now to be a general belief, in the West particularly, that the Dutch are the most profitable milk cows. Perhaps it is true, but the people will demand the proof, and so far there is very little evidence to base such an opinion upon. Tests have been made in abundance, but in very few instances has the milk-product been compared with the food consumed, and in no case that we have seen, has the actual food value of the milk been demonstrated, and it is especially important that this should be compared with the food consumed. The time certainly is favorable for tests of this kind, and we feel that the thought and labor of good breeders can be expended in no other way so profitably.

Growing Pumpkins with Corn.

Pumpkins are valuable for stock in autumn and early winter, or as long as they can be conveniently kept, though the amount of nutriment, in proportion to bulk to be taken care of, and their liability to decay, have led most farmers to discard them, and adopt roots or squashes for succulent food. As a rule, every crop needs all the ground it occupies, and all the air and sunlight available. Corn is a "sun plant," and to shade the soil and the lower stalks with the dense foliage of pumpkin vines, must be more or less injurious, even if the latter do not rob the former of any needed nutriment. On very fertile, new soils, with short-stalked varieties of corn, in localities where frost is not to be feared, it may be allowable to plant pumpkin seed at the second hoeing, in every third or fourth hill, in each second or third row. With favorable weather, the corn will produce about the usual yield, and after the early gathering of the corn, the growing pumpkins thus exposed to full sunlight, will ripen up those pretty well developed. As a rule, let the pumpkins have the whole ground; but still better are the harder fleshed squashes, which will probably supply more nutriment than field pumpkins, whether for man or beast.

SAVING CROPS AND STOCK FROM FRESHETS.—It is very hard, after having raised crops or stock, to see them swept away by a flood, as very many have done during the present year. Those having farms on low lands liable to overflow, destroying grain or drowning stock, can provide against such loss thus: Select the highest spot of ground, and grading up with plow and scraper a narrow driveway above high water mark; then build on each side of this driveway on posts set in the ditches,

made by the scraper, the cribs for grain, and the stables and pens for stock; also platforms for hay and grain stacks. This work can be done at the most leisure season of the year, and would not cost much more than the same preparations for farm animals made on the level ground. F.

Simple Carriage for Plows, etc.

Even where there are no stones, the common "stone-boat" is always convenient on any farm, for taking plows, harrows, cultivators and the like, to the field or from one field to another, over roads, grass, and soft ground. For common plows we have used a simple wooden shoe made with an axe in a very few minutes. Split one-third from the upper side of a round stick from the wood-pile, three or four feet long, and five to ten inches in diameter. Cut a notch two or three inches deep, a foot or so from the front end, and split off another piece down to this notch. With the corner of the axe, or a chisel, cut a small notch in the elevated front end to receive the point of the plow. Round up the front like a sled runner, and the thing is done. If preferred, use a large stick, and flatten the bottom of the shoe to give a broader base.

Mr. Reuben Harlan, Covington, La., recently saw a plow carriage on a Southern plantation. It was a plank of hard-wood eight feet long, a foot wide, an inch and a half thick, rounded in front like a sled runner, that it may easily pass

A PLOW SHOE.

over roots, stones, etc. A piece of trace chain, eighteen inches long, is fastened to the plank with staples, 18 inches from the front end, leaving it loose for the plow point to slip under a little distance. Pressing the handles will lift the front end to pass over large obstructions. The plowman can ride on the rear. Mr. H. says, "he has seen ten plow teams thus rigged coming in from a cane field on a gallop, and by the dexterity of the driver, the plows were thrown from side to side, and jumped gullies, roots, etc." Experience is the best test, but a plank four feet long would seem to be preferable, leaving lazy drivers no chance to ride, as it would be hard on a weary team to drag a man's weight on a plank having so large a friction surface.

Mode of Planting Peanuts.

B. W. JONES.

Peanut planting is done any time in May. The ground should be ridged and otherwise broken by plowing several weeks beforehand. Soil suitable for the peanut does not harden or pack much under rain and sun.—The best soil for this crop is a white or chocolate-colored sand. Some prefer a reddish sand, but that is more likely to color the peas and make them less salable. Any dry, open soil, having plenty of lime in its composition, will produce good peanuts. It should be clear of weeds and other coarse rubbish; hence ground in corn, potatoes, or some cultivated crop last year, is preferred. In planting, the ground is marked in rows about three and a half feet apart, and if any fertilizer is used it is applied in the drill before ridging. The ridge is formed by running a light furrow on each side of the drill, lapping the dirt in the middle. These ridges are afterwards knocked down nearly flat, by drawing over them from end to end a tolerable heavy pole, or board, or piece of scantling, attached to shafts or small poles for the horse. This is long enough to reach across two, three, sometimes even four ridges, and they are flattened so as to leave only a little elevation to keep the seed out of water in case of a heavy

rainfall before it comes up. Some dispense with ridges, and lay the seeds flat on the surface, only pressing them slightly with the foot. This saves labor, but as a rule the ridging is best. For this the same plow is used for the furrows as for corn or other crops.—The distance apart varies considerably, ranging from ten to twenty inches. Sixteen inches is a fair distance for the hoe in weeding, and for spread of vines on land of medium quality. An implement with a wheel is pushed along the ridge, points or pins at given distances marking the place on top of the ridge for the peas. Care is taken not to have the holes more than two inches deep. The pea, a single kernel in a place, is then dropped by hand and covered by carefully pressing a little soil upon it. The land is left in a smooth state for the first plowing. Being a tropical plant, the peanut requires warm sun all the time. We have known it planted all through the month of June, but it should generally be up and growing by the first of that month here. Cold, rainy weather about the time of planting is very detrimental. The crop can be and is already grown successfully much further North than Virginia.

Simple Leveling for Draining, Etc.

For extended, expensive operations in draining, ditching, grading, irrigation, and the like, it is cheapest in the end to secure the services of a civil engineer or good surveyor with delicate instru-

Fig. 1.—AN EASY METHOD OF LEVELING.

ments. But for ordinary farm draining, ditching and grading, most men can extemporize simple apparatus, or borrow a common spirit level from a carpenter. We have secured quite accurate results thus: Select a perfectly straight thick board or plank four feet or more long, of any width above five inches, the upper surface planed smooth. If not already painted, rub a little oil over the top, wiping it clean. Lay this upon or near the ground as near level as you can.—Pour half a teaspoonful or so of water upon its middle, covering four to six inches lengthwise and two or three inches wide. Carefully elevate any side or end needed to bring the edges of the little pool of water to an equal

Fig. 2.—A CHEAP LEVEL.

thickness. One can sight along the upper side or an upper corner, to within an inch fall or rise in one to two hundred feet, as in figure 1. An assistant at *a* marks the place on the stake, a motion of the hand up or down directing him to raise or lower his finger. Other stakes at *b*, *c*, *d*, etc., can be marked to show the elevation of this surface at each point, and how deep to dig. It is well to try the board elevated on sticks or stocks at *a* and sight back, to test the work.

A very simple home-made leveler we have used with much satisfaction is made thus: A cross-piece

Fig. 3.—LEVEL IN SHAPE FOR DRAINING.

of inch stuff, four inches wide, three to four feet long, is firmly nailed near the top of a similar piece five feet long, sharpened at the foot, with two bits of blocks in the corner if it be much used, to give it firmness. A scratch-all mark runs exactly down its middle front, with a small pin at the top, from which a strong thread or light cord is suspended with any convenient weight on its lower end. With the cross-piece exactly at right angles to the upright, easily secured by using a good steel square, it will be level when the plumb-line coin-

cides with the mark, running the length of the upright bar, and may be sighted along its upper edge.

"Picket," Morrisonville, Ill., sends us his plan, which is essentially a long sixteen foot fence board,

Fig. 4.—LEVELING WITH CARPENTER'S LEVEL.

perfectly straight edged, with two laths nailed on each side of the center as a handle (figure 2). This is set on edge, and upon the middle of its upper edge is placed a "fifteen-cent pocket level." The longer carpenter's spirit level would be more accurate. When the fall is decided upon, another board is cut to move along the bottom as the drain is dug. Thus if the fall is two inches in sixteen, and a sixteen-foot board is two inches narrower at one end when the top is kept level the bottom edge moved along the excavation will indicate the proper shape, as in figure 3.

Mr. J. Bartlett, Oshawa, Ont., sends us sketches which we combine in figure 4. Let *s*, *s*, be the irregular surface; at the highest point set *a* four feet high, and with a carpenter's level, mark *b*; then mark *c* four feet below it on the stake, which may be one hundred feet or more away. From the distance between *c* and *s* judge of the fall necessary to have the drain sufficiently below the surface at that point. If this be say two feet, mark *e* two feet below *b*.—Then at various points as at *f*, *g*, *h*, *k*, etc., twenty to thirty feet apart, set stakes marking them in the line between the eye and *e*, either by sighting with an assistant, or stretching a line. The drain *d* will be equally distant below the tops of these stakes. A line stretched between the tops of these, or near the ground at equal distance from the stake tops will serve as a guide for the bottom of the drain at all intervening points.

The Care of Fruit Trees.

PROTECT THE ROOTS.—In transplanting or handling trees, recollect that every minute of exposure to the air injures them. If a tree can not be planted at once, make a hole and bury the roots. Those who go to a near nursery and take home their own trees, should puddle them. Make a hole in the ground a foot deep and as large as needed. Have a plentiful supply of water. Pour water into the hole and stir up the soil, until a thin mud is formed. Draw the roots of the trees through this, until they, even the smallest, are completely covered with mud; then sprinkle dry soil over them to dry them off. This "puddling" or "grouting" of the roots, as the English call it, is useful not only for trees, but for plants of all kinds.

PASTURING THE ORCHARD.—It is a singular fact that the orchard is the only field that farmers, as a general thing, expect to yield more than one crop. There is so much apparently unoccupied ground between the trees, that there is a desire to utilize it with some crop. When the trees are in bearing, they need all the soil. While the trees are young, a manured crop may be grown between the rows. The best treatment of an established orchard is, to sow it to clover and pasture young pigs upon it. By this the fruit, soil and pigs will be benefited.

STAKING NEWLY PLANTED TREES.—In exposed localities, trees are apt to get a "list" in the direction of the prevailing winds. If the trees are small and properly pruned at planting, there will be less trouble than with large trees, which must be staked. The safest way is to drive two stakes at a little distance, upon each side of the tree, and secure the trunk to both stakes by means of a straw band, or soft rope so as not to chafe.

INJURED TREES.—Nursery trees when sent a long distance, may be injured by drying, and when received, the bark will be shrivelled, and the tree

apparently dead. Such trees may usually be saved. Open a trench large enough to receive them, and lay in the trees, root and branch, and sprinkle in the soil among the branches, laying the trees one upon another, taking care to have the soil come in contact with even the smallest branches. The bark will gradually absorb moisture from the soil, and in a few days become plump and apparently as bright and as fresh as ever.

STARTED TREES.—If trees are transported in warm weather, especially if packed moist, the buds will push, and when unpacked will be found to have white, weak shoots, several inches long. The only way to save such trees is to cut back every branch to a good bud that is still dormant.

Selling Eggs by Weight.

There is from twenty to thirty per cent difference in the weight of eggs, yet the custom is almost universal in the Eastern markets, of selling them by the dozen at a uniform price. Even ducks' eggs, which are much larger, and by some regarded as richer, bring no more than the smallest hen's eggs of not half the weight. In California, eggs, fruits, and many other articles that are here sold by the dozen, the bunch, or by measure, are sold by weight. The practice is a good one, and works beneficially for all parties, especially for the producer. It operates as a premium upon the cultivation of the most productive varieties of fruits, vegetables, and farm stock. The farmer, who is pains-taking with his poultry and gets the largest weight of eggs, has a fair reward for his skill and industry. The present custom is a premium to light weights, and good layers. We need a change in the interest of fair dealing in trade, and, if necessary, it should be enforced by legislation. If the legislature is competent to fix the weight of a bushel of corn or potatoes, it can easily regulate the weight of a dozen eggs, and thus promote exact justice between buyer and seller.

Stool and Clamp for Harness, Etc.

Mr. C. B. Clark, Peoria, Ills., sends us a description of a combined bench with simple clamp for holding harness and other articles for repairing, etc. The bench or stool *b*, of any desired size, is supported by two legs near one end. The other end is held up by the foot of the long claw, extending to a convenient height for the operator. A

A HARNESS STOOL.

shorter claw, *c*, is fastened to it by a cross-piece *p*, about an inch thick and three inches wide, passing through a slot in the jaws, in which it works easily but firmly on two iron pins, a little more than halfway up from the bench. In the lower end of the short jaw an eccentric works on a pivot and against a projection on the larger jaw. Depressing the handle to this eccentric or cam closes the jaws at the top with all the force desired.

What are English Horse Beans?

Beans are so often mentioned by English writers for their great value as food for horses, that occasionally some one in this country wishes to try them and asks about the variety. The English Horse Bean is not, as some suppose, a variety of our field bean, but a very different plant, belonging to a different genus. This is a variety of what, in its garden forms, is known as Windsor Bean, Magazan Bean, etc. The stalk is erect, stout, simple, and three feet or more high, with no sign of twining stems; the leaves are of the shape shown in the engraving; the flowers, in clusters in the axils of the leaves, are followed by thick fleshy pods.

THE HORSE BEAN

The seeds (a.) are flattened and brown; those of the horse beans being not one fourth as large as the garden varieties. They contain a very large amount of nitrogenous matter, but are rather indigestible; on this account, when fed to horses, they are mixed with two or three times as much oats. The horse bean has been tried occasionally in this country, but our hot weather stops their growth before they have attained their full size. In trying the garden varieties we have found them to become so infested with plant lice, that growth was impossible. It is not at all likely that this bean can ever become one of our farm crops.

Shade Trees—Planting, and After-care.

REV. J. W. GUERNSEY.

In no other way can we, with so little expense of time, labor, and money, add so much to the comfort and pleasantness of our homes, as by the judicious use of shade trees. Once set, nature will keep them in repair, adding some new beauty of form and repainting them with her choicest colors every year. On the north side of buildings, to break the wind, evergreens are to be preferred; and of these the hemlock is the best. For shading, deciduous trees should be used, which will shut out the sun in summer and admit it in winter.

Where there is room enough for them to grow to their full size, the maple and elm are, undoubtedly our best trees; but if they are to stand near a house, some smaller tree should be chosen. Both maples and elms, when set for shade, are liable to be ruined by two things, neither of which affects them in the forests. Borers, beginning near the ground, work their way upward in an irregular course; sometimes nearly encircling the trunk before they come to the surface, and carrying sure death along their entire track. The only remedy is to watch for them, and kill them as soon as they begin to work. The second danger is the starting of the bark, which is no less fatal. This occurs only on trees of a few inches in diameter, and on the south and south-west sides of such that are peculiarly exposed to the sun. When the tree is

frozen, a warm sun thaws a section of the bark, without thawing the wood beneath it; the vital connection is broken, and the bark and adjacent wood die. Small trees thaw through and escape injury, and large ones do not thaw at all at such times. Anything that will shade the trunk at the exposed points, will make it secure. The elm has a deadly enemy in the canker-worm, that frequently destroys the entire foliage from year to year, until the tree dies. The most usual remedy is to guard the trunk by some contrivance that will prevent the female moth, which is wingless, from ascending it. The Lever-wood, or Hop Hornbeam, is a hardy symmetrical tree of moderate size. Its branches and foliage are very fine. Its fruits, which resemble hops, are very abundant, and remain on the tree during the entire season; their modest russet beautifully combining with the deep green of the leaves. The birches, in their several varieties, combine, in an unusual degree, the requisites of a shade tree. They grow rapidly, are hardy, flourish on almost any soil, and are seldom injured by insects. The trunk is picturesque in its irregularity, throwing off numerous small branches, that divide and sub-divide into minute, flexible sprays, that sway in the breeze with infinite grace. The pearly white or bright amber color of the bark on the trunk and large branches, passing by insensible gradations through the various shades of garnet and brown, to the deep purple of the remotest twigs, is a beauty peculiar to these trees. They are among the earliest to put forth their leaves and the latest to drop them. The leaves are beautiful in form and exquisite in color; and when touched by the autumn frosts, their dying hues of burnished gold are scarcely less gorgeous than the royal crimson of the maple. Their swelling buds herald the approach of spring, long before the maple and elm have sented its coming. In the rigorous depths of winter they commence to hang out their pendulous flower buds, ready to unfold their modest blossoms in the first warm breath of spring. The minute sub-division of their branches secures a dense shade, even from a small top, and gives such flexibility that they are rarely broken by wind, snow, or ice. If a maple or elm is cut down, all that remains is an unsightly stump; but a birch stump will send up a cluster of sprouts that in a few years form a group of trees more beautiful, if possible, than the original one.

Trees that have grown in the open air, will do better than those from thick woods. In selecting, those only should be taken that are perfectly sound; a dead spot, however small, will extend until it ruins the tree. Trees with short trunks and large thick tops should be chosen, avoiding such as divide into two nearly equal branches, for they will be very likely to split down. In taking up trees, every root should be secured to the uttermost fiber as far as possible, and without splitting or bruising them, and the holes for planting them should be large enough to receive the roots in their natural position. While out of the ground, the roots should be protected from the air and kept moist, and in setting them fine rich earth should be packed around all the fibers. Trees should be staked to prevent the wind from starting the roots, and well mulched to keep the ground moist and loose. A vicious practice prevails very extensively of cutting off the entire top. This is the death warrant of the tree. It may put out new branches and do well for a few years, but the wound will seldom heal; there will be a dead stub above the new limbs, that will ultimately decay down into the center of the trunk and the limbs will break off or die. This process, in its various stages, may be seen in a large proportion of the trees that have been treated in this way. If a trunk must be cut off, let it be just above a thrifty limb, whose growth will heal over the wound. If branches must be removed, they should be cut close to the trunk, great care being taken not to injure the bark or wood, the cut made smooth and covered at once with wax or paint so as to exclude the air. Shade trees are usually set too thick, from two to four times too many being put on the ground; consequently, as soon as they have grown a little, they

interfere with each other, and a struggle for existence commences, in which all suffer and symmetrical growth is prevented. Trees should never be allowed to exclude the direct sunlight from a house; to do so, is to make it unfit for a dwelling. To remedy this by pruning, will leave naked trunks covered with unsightly scars, too large to heal over, which will ultimately decay and kill the tree. Thinning out is but little better, for the trees that remain will be stragglers standing at irregular distances, with forlorn and badly shaped tops.

Shade trees should be carefully watched, and all branches that start where they are not wanted, that will ever interfere with streets, walks, buildings, or other branches, should be promptly removed. Such branches are often neglected until their removal irreparably injures the shade tree. All dead limbs should be taken away at once.

Good King Henry.

A gentleman having seen "Good King Henry" mentioned as a useful garden plant, called at our office to learn more about his Majesty. Why the plant should be so named is somewhat obscure. One writer says that this was so called to distinguish it from another and poisonous plant, known as "Bad Henry," which does not explain why it should be a Henry, and a king at that. In some parts of England the plant is called "Good Fat Hen," which some have tried to explain by asserting that it was used to fatten poultry. As it is not known to be fed to poultry, this derivation is doubtful, and it is more likely that Henry was shortened into "Hen," than that it was derived from the food of hens. As to the plant itself, it belongs to the Pig-weed family. Linnæus recognized the common

GOOD KING HENRY (*Blitum Bonus Henricus*).

name when he called it *Chenopodium Bonus Henricus*. Though later botanists have placed it in the related genus, *Blitum*, it still retains the original specific name, and is now *Blitum Bonus Henricus*. The plant is a native of England, and is very sparingly naturalized in this country. It has a perennial root, and its stem, from one to three feet high, branches but little. The shape of the leaves, etc., is shown by the engraving of the upper portion of a plant. It is, like the related Pig-weed, Goose-foot or Lamb's-quarter, very acceptable as greens,

for which use it is cultivated in parts of England, and occasionally in this country. The seeds are sown in a seed-bed in spring, and when large enough, the plants are transplanted to rows fifteen inches apart, and set every ten inches in the row. The leaves are fit for use the following spring, and are cut as soon as large enough. It is also called in England, Perennial Spinach, All Good, Tota Bona and Mercury. The last name is in parts of this country applied to the Poison Ivy. The origin of the common names of plants is puzzling!

Some Useful Ornamental Shrubs.

The value of ornamental shrubs is not generally appreciated, perhaps because the better kinds are not popularly known. Lilacs, Snow-balls and a few others, are found all over the country, but the

which should be cut back to keep them within bounds, or they may be trained like those of Golden Bell, against a fence or a low trellis. The light orange-colored flowers are produced all summer.

THE MOCK ORANGE (*Philadelphus*), often called *Syringa*. There are several of these, which produce an abundance of their pure white orange-like blossoms in summer. Some are pleasantly scented, but those with the largest and whitest flowers are not so. One of the finest is Gordon's Mock Orange (*P. Gordonianus*), figure 3, a native of Oregon. It blooms ten days later than the others, and its large flowers, of a very pure white, are slightly fragrant.

THE WEIGELAS.—When Mr. Fortune introduced these plants from China and Japan, he did a great thing for our gardens. They were first called Weigelas, and later were placed in an older genus, *Dier-*

coming into bloom, to enable one to make a selection, that would afford a wealth of beauty every week in the North from April to October, and for some months longer at the South. Then the variety that is afforded by different forms, habits, and sizes of such plants, the colors and shapes of the leaves, branches, and the ornamental fruits of some, is very great, and adds to their beauty and interest. The evergreen trees and shrubs must also be mentioned for the peculiar attractions they contribute throughout the entire year. Then there are the hardy climbers—a most useful and easily managed class of ornamental plants, and the aquatic, bog, and rock-flowering plants and ferns, all of which possess value for special uses. Besides the hardy kinds, possessing permanent value, there is an endless assortment of annual and perennial plants, raised each year from seeds, bulbs, cuttings, or in a green-

Fig. 1.—GOLDEN BELL.

Fig. 2.—JAPAN GLOBE FLOWER.

Fig. 3.—GORDON'S MOCK-ORANGE.

Fig. 4.—ROSE OF SHARON.

newer sorts are slow in making their way. Many an owner of a city or village lot, and many a farmer with a neglected front yard, would be glad to beautify them and make them attractive, if it were not so much trouble to keep them in order. The first requisite in a village or country front yard is grass. A good turf being provided, a few clumps of shrubs will be all the ornamentation needed. If flower-beds can be taken care of, all the better, have them by all means, but grass and shrubs will make the place satisfactory to the owner, and a delight to the passer by. Our swamps, thickets, and woods, will furnish those who search for them an abundance of fine shrubs for planting in the grounds. But every one can not spend time in collecting these, and must obtain their material from the nurseries, where there is a great variety from which to select. We point out a few really good and useful kinds that may be readily obtained, and which ought to be more generally known.

THE GOLDEN BELL (*Forsythia*).—Very early in spring, before the leaves appear, these Japanese shrubs hang out their golden yellow bells. The two most cultivated are the dark-green (*F. viridis-sima*), and the Hanging Golden-bell (*F. suspensa*), figure 1. Both have long slender branches which bend gracefully, and in the latter especially, touch the ground. They may be kept in the shrub-form, by close pruning, or be trained against a building.

THE JAPAN-GLOBE-FLOWER (*Kerria Japonica*).—The flower of this in its single state, looks like a large yellow blackberry-flower; that form is rare. The kind that has long been in gardens is double, and more common. The flowers are so double that they look like little golden balls or globes, figure 2. These are borne upon long, slender, green stems,

but they may well retain Weigela as a garden name. The first introduced was *W. rosea*, but now the catalogues offer over twenty species and varieties, with flowers from pure white to the deepest purple, and some have handsomely variegated leaves. They bloom in June and July, and continue long. A clump of different kinds is a grand sight. They are improved by severe pruning.

THE ROSE OF SHARON, also called shrubby *Althæa*, is one of the oldest of garden shrubs, yet has in recent years been so greatly improved, as to be more valuable than some novelties. Its blooming in August and September, gives it a special value. The proper botanical name is *Hibiscus Syriacus*. The flowers, as large as Hollyhocks, are single (fig. 4), and double, from pure white to dark-red and purple. It must be severely pruned. A variety of this is one of the best shrubs with variegated foliage in cultivation. This small collection of shrubs covers the season from earliest spring until frost. Other selections could be made to do the same, but these are chosen because they are effective, easily cultivated, and cost but little at the nurseries.

Variety in Ornamental Planting.

ELIAS A. LONG.

There are no good reasons for the prevailing lack of variety in the trees, shrubs, and other materials employed in making American homes attractive. Among the many hundreds of trees, shrubs, and flowers, that are hardy in nearly every part of this country, and which are now kept for sale in the leading nurseries, there is in the matter of flowers alone, for example, a wonderful variety. There is enough difference among these in their season of

house or window-garden, that are easily grown, and which serve to render the garden gay for months in the summer, with their characteristically bright flowers. Now all these things are so easily and cheaply procured in the nursery and seed establishments, that no one who has a plot of land surrounding the house should put off for any length of time, the setting out of a sufficient assortment to amply embellish the place throughout the entire year. To make the surroundings of one's home attractive, will pay in dollars and cents, besides contributing to the enjoyment. The writer but recently attended the appraisement of some ornamental trees, twelve years planted, that had to come away on account of the widening of a street. The amount allowed the owner as a remuneration for individual trees was as high as seventy-five dollars each. The same trees when planted perhaps cost one dollar each, and the labor of setting, say one-half as much more. It was their worth for shade and ornament that governed the price. There are few places where the presence or absence of fine trees and shrubs would not similarly effect their valuation if sold. If there are children, judicious investments in beautifying the surroundings, will afford invaluable returns in cultivating in them a love for and an interest in natural objects; inspiring in them a desire for the study of botany and natural sciences, than which nothing is more pure and satisfying for young minds. There is much complaint of the inclination of the young to leave rural homes for town life. Nothing would be more potent to arrest this tendency, than to spend some money and time in rendering the home attractive by the means that have been suggested. Resolve to set out and properly attend to a suitable selection of trees, shrubs, and flowers,

Holders for Whisk-Brooms.

Whisk-broom holders like figures 1 and 2, when neatly made, are quite ornamental and very useful. They are appropriate for a bedroom or hall. The hack of figure 1 is wood, cut out with a fret saw, and has a simple pattern around the edge. Walnut, imitation ebony, or other dark wood, is preferable to holly or other light color, as it shows dust and soiling less plainly. Midway between the top and bottom, and at an equal distance from each edge, cut two slits just large enough to let the embroidered band slip through. For the band work with bright-colored silk a strip of velvet an inch and a half wide. The ends are passed through the slits and fastened on the back with very small tacks, making a loop on the front just large enough for the broom to be slipped in half its length, and pulled down through it when taking it out for use. Figure 2 is entirely of home manufacture. Two pieces of heavy pasteboard are cut to a true circle of the right size by marking around a dinner plate

Fig. 1.

Fig. 2.

and using a sharp knife or scissors. Each piece is covered with gray linen, and the front one is bound around the edge with narrow blue ribbon. The band is a strip of gray canvas, worked with blue, rose color and yellow, and is sewed to the front piece. Sew two bows of blue ribbon near the upper edge. The front and hack pieces are then stitched together over and over with silk the shade of the ribbon. It is suspended on a loop of ribbon with a bow at the top sewed on the hack. T. K. Y.

Mantel Lambrequins—Catch-Alls—Splashes.

The various tasteful articles, now so common, which make home attractive, are not always within our reach, however great may be our love for the graceful and beautiful. Your friend's handsome cushion, or screen, or hanner, seems a small affair of plush, or velvet, or gay ribbon, etc., but when one counts up the bills of pretty materials, the embroidery silks, the fringes, the this, that, and the other, needed in the construction, the sum is frequently more than the small purses of economical folk can afford. Yet we all want some pretty things about the rooms, some things that small means, and fragments of time can compass, and we can have them. The present style of short lambrequin, or drapery for the middle of the mantel, on which a clock or other heavy article may stand, can be easily made of almost any heavy cloth, of desirable color. It may be a piece of black broadcloth, with cretonne flowers or figures cut out, and outlined with embroidery silk for a border. Or you may with the Diamond Dyes, now so much used, color the cloth to suit the fancy or the furniture. Lay on a piece of black velvet ribbon an inch wide, or wider if you prefer, about two inches from the edge of the lambrequin, and with bright

embroidery silk, of good contrasting color, herring-bone across the velvet, or catch the edges.—A neat pocket, or "Catch-all," may be made with an old straw hat, especially one of mixed braid, by lining it with turkey-red calico, and bending the front lower than the hack, fasten it to the wall. A bunch of dried grasses, held with a bow of bright ribbon, gives a pretty finish to the front.—A neat Wash-stand Splasher may be made of a piece of éru or buff linen, such as is used for window-shades. Indeed, a piece of an old window-shade will answer, if stiffly starched. Cut the length and width desired, hind with scarlet skirt-braid, or carefully cut a scalloped edge. From some gray cretonne, cut a graceful spray or bouquet of flowers, and fix them with mucilage firmly in the corners of the splasher. Put on also a small center piece of the same and you have quite an addition to your room.

LUCY RANDOLPH FLEMING.

Home Hints.—Clothing, Etc

The prevailing style of hair dressing for ladies for sometime past has been a twist or braid knotted low in the neck. This has not been hecoming to many, and there is a prospect of a return to the other extreme—wearing the hair very high on the top of the head. Of course very young ladies will retain the recent style as most youthful. Misses wear one or two long braids tied with ribbons. Some braid them half way and leave the ends curled. It is said that curls, which have been laid aside so many years, are coming back to be the "rage." This will be welcome to those who, for fashion's sake, have tried so hard to thwart nature by brushing and combing to straighten their natural curls. Children still wear their hair hanged, *à la* Esquimaux, to the ears, and long behind. Some physicians condemn bangs as very injurious to the nervous system, and in several known cases of spasmodic nervous affections parents have been advised to put the hair hack from the forehead. The round comb is used for this. "Frizzes" of some kind are becoming alike to old and young, and the cases must be rare where one has not enough hair of her own to use for this purpose. The frizzes should be light and simple. The fashion of covering the forehead nearly to the eyes with "front-pieces" or "wigs" is simply hideous, and every real lady will prefer to make the most she can of what nature has given her and be satisfied. A very little hair will look a great deal more if dressed in puffs which are always ladylike and becoming. Fancy combs and hair pins are much used as ornaments, and are in every style from the pretty imitation of shell to those of silver filigrees in exquisite flowers or gold set with pearls and diamonds. But every one should study her own style, and so adapt the manner of dressing her hair to it, that no special attention shall be drawn to her by any attempt to follow a fixed fashion merely which may be becoming to one and very unbecoming to another.

"How shall I make over last season's dresses for my children who have outgrown them?" is the perplexed mother's query just now. The pretty and favorite guimpe will help out here. This is a white waist, with or without sleeves, made plain or tucked and trimmed with insertions. It is cut three or four inches longer than the waist line, and a facing is put on through which a string is run to draw up at the waist. The overdress is a plain princess style, or a gathered waist with a belt, either of them cut low in the neck, with shoulder straps or puffs. The sleeves may be retained if preferred, and a white cuff added to match the white waist. The straps or puffs will lengthen the dress as required. Another way is to insert a yoke of Hamburg embroidery. This comes now in very handsome patterns for yokes, sleeves, and apron fronts to white dresses. White dresses are much worn in the warm season and are becoming, both to young and old. There is a large variety of fabrics. Satteens, which are so pretty in colors, are equally so in white; they are plain, striped, dotted, checked, in blocks, and also corded. In ready-made white dresses poor Victoria lawn has been used. There is now a new fabric called "India

linen," which is much better, though it is really cotton. White dresses can be bought very cheaply, ready-made, but of course they are much more desirable if home-made. They should be simply made, but of good material. Colored satteens are very handsome on pale tinted grounds, with designs of flowers, leaves, fruits, acorns, berries, etc. Some have Japanese designs of birds or human figures, and others of miniature landscapes. They cost thirty to fifty cents a yard. Some make them up with plain goods to match, but they are usually made of one piece. The style is a plain, unlined basque, a short round skirt with ruffles, and a plain hemmed overskirt much puffed, but arranged to draw up with strings. Laees trim these dresses showily and come in gray and cream color as well as white.—Little girls and boys wear in all seasons every day costumes of wool, in dark blue or black trimmed with braid, housse shape, with a plaited skirt for girls, and Knickerbockers for boys, with long stockings to match.

For spring outside coats for children and young ladies the redingote is most suitable. All dark colors are fashionable, and if plain have collars and cuffs of velvet. For travelling and very common wear they are made of checks and plaids, trimmed with the same goods. Little girls have often a small cape added, with a plaiting around it three or four inches wide, or trimmed with velvet. For little boys the ulster shape, double-breasted, bound with braids and with nice buttons, is always appropriate.—Pretty, soft caps, and a variety of Derby hats, go with them from which to choose.

ETHEL STONE.

A Curtain Screen for Doors.

It frequently occurs that a bedroom has no communication with the hall, except by passing through a parlor or sitting room, in sight of persons chancing to be there. If the bedroom and hall doors are near the corner, a convenient plan is to run a rod across, as in the engraving, and upon this hang a curtain of woolen stuff or chintz, by rings, so that it can be shoved to either side when not

A DOOR SCREEN.

needed to form a screened passage. Furnishing stores supply such rods with hooks to hold their ends, or one of wood may be readily turned, or worked out in a carpenter shop, to be stained and oiled.

A Home-Made Refrigerator.

A very useful ice box can be made out of an ordinary dry goods packing box. Mine is three feet each way. Inside of this is another rough pine box two feet each way. The side spaces and six inches at the bottom are filled with sawdust. The inner box is covered with tin internally and painted white. The cover is two feet ten inches each way, and double, with six inches of sawdust between the boards. It is fastened to the hack of the ice box with strong iron hinges, and being very heavy it has pulleys with weights to raise and lower it. The pulleys may be in the top of uprights nailed to blocks on the back, to be out of the way of the cover, or they may be suspended at any convenient point where the weights can descend. When shut down the cover fits in tightly, and is

flush with the top of the outside box, and lies closely upon the top of the inner box to exclude air, an important point. The whole affair can be put together in a few hours by any skillful man on a farm. It is best to have cleats nailed to the sides of the ice chamber to support a shelf made with wooden sides and galvanized iron rods or large wire

Fig. 1.—THE REFRIGERATOR.

in the center, and handles or holes on two sides to lift it by. Large blocks of ice, the larger the better, are laid in the bottom, which should slightly incline so as to run off all drip water, a few sticks being placed in the bottom for the ice to rest on. I have the drain pipe constantly open, and find the ice keeps longer if not in its drip. This is an excellent refrigerator if ice in good-sized blocks is supplied liberally, say every two or three days in very hot weather. On the tray with two large blocks of ice below I have kept delicate fish quite fresh for ten days in the hottest weather. The constant good circulation of air in the box leaves

Fig. 2.—THE TRAY.

no close, musty smell as is common in ordinary refrigerators. At first I covered the sawdust all around flush with the top of the inside box with tarred felt, but found this did not answer well, so I subsequently placed a board cover over the felt.
St. John's, Newfoundland. D. W. P.

A Chapter on Potatoes.

MARY WINCHESTER.

PLAIN BOILED.—Wash and clip a bit from each end and drop into boiling water. Add a little salt, and cook until done. If poor and watery, peel and let them lie in cold water an hour or more before boiling. When done pour off all water, remove the cover and shake and toss them in the kettle before an open window or door, which will make them mealy.

BAKED.—Wash and boil until nearly done, then bake. They are much whiter and mealier than if simply baked, and it is quicker and takes less fire.

MASHED.—Peel, cut out all imperfections and boil in water a little salted. When done pour off the water and set the kettle off the fire, but where it will keep warm and mash thoroughly. Add sufficient hot milk to moisten, also a small piece of butter, and continue working until white and creamy. Serve while hot. Cold mashed potatoes may be cut in slices, dipped in beaten egg and fried in nice fat or dripping.

POTATO AND ONION STEW.—Slice raw potatoes and onions to one's liking, and place them in a stew pan. Cover with boiling water and cook tender. Season with salt and pepper and a little butter.

SARATOGA POTATOES.—Peel and slice very thin, and drop into cold water a few minutes. Drain and dry them in a towel. Have ready a saucepan of boiling lard, drop in the slices and fry a light brown. Lift them out with a wire spoon, drain in a colander, sprinkle a little fine salt over them evenly, and serve very hot.

DUCHESS POTATOES.—Rub one quart of hot boiled potatoes through a colander. Mix well with them one ounce butter, a scant teaspoonful of salt, a pinch each of white pepper and grated nutmeg and the yolks of two raw eggs. Pour the potato on a plate, and, with a knife form it into small oblong cakes; lay them on a buttered tin, and brush them over with beaten egg and color a golden brown in a moderate oven.

NEW POTATOES.—Wash, scrape, boil ten minutes; turn off the water and add enough more boiling hot to cover, with a little salt. Cook a few moments, drain and set on the stove again. Add butter, salt, pepper, and a gravy made of about two tablespoonfuls of flour to a pint of milk. Or, when cooked and drained place in a skillet with hot drippings, cover and shake until nice brown.

POTATO SALAD.—Boil one egg very hard, rub the yolk fine, add one raw yolk; one teaspoonful each of corn-starch or fine flour, vinegar, sweet oil and salt, half teaspoonful of mixed mustard, a little cayenne pepper, and two teaspoonfuls of butter. Beat all very thoroughly together to a smooth paste. Slice cold potatoes thin, arrange in pyramid or mound-shape, and pour the mixture over; ornament with slices of boiled eggs, parsley, radishes and lemons as you fancy. Serve cold.

POTATO SOUP.—Boil one quart of milk with a little mace; boil and mash finely four good-sized potatoes, add a little butter and salt; pour the milk over the potatoes and strain. Beat three eggs well in a soup tureen. When ready to serve pour the soup over the eggs, heating them while doing so, and send to the table at once very hot. Season with celery or onion, or both.

POTATO SOUFFLE.—Boil six ordinary-sized potatoes, rub them through a sieve. Scald a teaspoonful of milk and a tablespoonful of good butter, add to the potatoes with a little salt and pepper and heat them to a cream. Add the yolks of four eggs, one at a time, heating them thoroughly. Drop a small pinch of salt into the whites and heat them to a stiff froth, adding them to the mixture, heating as little as possible. Have ready a well-buttered baking dish large enough to permit the souffle to rise without running over. Bake twenty minutes. Serve as soon as taken from the oven, and in the same dish in which it was baked.

Make the Kitchen Pleasant.

EBEN E. REXFORD.

In most country homes, the kitchen is the most important room of the house, where more than anywhere else the family gathers, and the most time is spent by the house-keeper. First of all, let it be arranged as convenient as possible for work done there, and to save steps. Next let it be pleasant and home-like. Even if the family do not frequent it, it ought to be cheerful and bright for the sake of those who pass their chief time there. A picture on the wall will rest a weary eye, and be educating to those busy at work. Too often the kitchen is a cheerless place, associated only with hard, tread-mill work; no brightness on the walls, no easy chair inviting rest in its broad arms at spare moments; no paper to read in the little "between whiles."—Keep its walls sweet and clean with white-wash. I do not like paper on kitchen walls. If white is objected to, get alabastine for tinting them any color desired. A huff tone makes the room bright and sunny. Have the lower part darker, if not finished in wood, which is always preferable for many reasons. Beautify the windows in summer by training vines about them outside, and in winter with simple pretty lambrquins. If you want the room to have a shut-in cosy look at night, use Holland shades, to be drawn up or down as required. The kitchen cannot be too light. Hang pretty pictures on the walls. They need not be expensive; really good ones can be cut from some of the illustrated papers of the day. The father or sons can frame them cheaply. Have a lounge, and a rocker with soft cushion, a broad back, and wide, comfortable arms. A hang-

ing lamp, that can be lowered or raised at pleasure, is a convenience for any room, the kitchen included. With everything clean and neat, as every house-keeper taking pride in her work will be sure to desire it, she will not be ashamed to receive unexpected visitors there.

A Stand for a Night Lamp.

Where a light is needed during the night for a sick person, especially if warm water or medicine be needed, and for an infant requiring warmed food, a stand something like the one here sketched will be found quite convenient. The ends may be of half or three-quarter inch clear pine, cut to any

A NIGHT LAMP STAND.

form desired, and with one or two shelves, according to whether the lamp used be a tall or low one. The height needs to be such that when the lamp is on the shelf, the end of the stand will hide the direct rays of light from the sleepers. Two stout wires or small iron rods, placed lengthwise across the top, support a tin or other vessel containing water or food. The lamp can be turned down so that a very small flame, two inches or so below the vessel, will keep the contents at the desired heat. If for continuous use, the stand can be stained to imitate the furniture, and varnished; for temporary night use, it may be left plain, to be set away out of sight during the day.

Out-Door Seats.

There is an infinite variety of simple, cheap, convenient, home-made seats, that may be provided for a shady spot on the lawn, in the door-yard, in the garden, fruit orchard, etc. Figure 1 is a frame of saw-horse pattern, with two strong pieces in the upper corners, over which is stretched a canvas or heavy sacking having eyelets worked along its two ends. A cord through these can be drawn to any desired tautness. This may be of any size, from

Fig. 1.—A SAW-HORSE SEAT.

a camp-stool to a cot or lounge, and be of colored or striped material, with stained or painted frame. Figure 2 may be a natural stump, with a board or

Fig. 2.—A STUMP SEAT.

plank spiked to its top sawed off level. A stump may be brought from the woods, its larger roots cut off for feet, and its top for the seat board.

Kittie's Lesson.

"Pease Kittie, tum an pay wis Daisy!"—It was a sweet, pathetic little voice; but Kittie, comfortably reclining on a couch, improvised from a blanket and pillow, never glanced from her book to the coaxing little petitioner, as she answered dreamily, "Pretty soon, don't tease!"—"Tan I have your beads to string?"—"No, you would lose them."—"Den tan I pay wis the dollies?" her chubby hand tenderly smoothing two china ladies in gorgeous pink and blue gowns that were repos-

two large wings, taken from an eagle their father had shot, which usually adorned the walls. Hardly knowing what she did, Kittie ran to the window which opened upon a sharply sloping roof, and almost fainted at the sight of Daisy with the huge wings fastened to her shoulders balancing on the edge of the roof. With rare presence of mind she stifled a cry; but the child saw her, and called gaily, "See Kittie, Daisy not to be a hizzer any more! She doin' to fly away to heaven," at the same time holding out her short skirts, and dancing on her tip-toes.—With great effort Kittie restrained her voice, realizing that the least start might indeed send the little sister to heaven, but she said gently, "Oh! darling, come back; you shall play with Angelina and Seraphina all the afternoon."—"Weally!" and the dimpled face beamed with smiles, "Den I dess I'll not fly till anozer day; but it's dreadful slippery here."—"Wait till I come to you."—But it was only by means of a stout rope that Kittie succeeded in getting the child safely within the window. That evening the mother clasped her baby tightly as she listened to

ton's were moving to a new home nearer the village.—"I hep mamma!" lisped Dolly, just as Mrs. Dayton entered the room with a troubled face, and said, "Maud, Nancy, I am so sorry to disappoint you, but one of you will have to stay home to-day."—A doleful "oh, why?" echoed through the chamber, and two dismayed girls stood aghast.—"I find I must go over and see to things at the new house; the men have already broken my little sewing chair all to pieces."—"What a shame!" cried Maud.—"And some one must stay with Dolly and Dot. I think it better be you, Maud, as Nancy remained home from the fair last week."—"O, dear! I can't," exclaimed Maud, "why I have thought of nothing but this May-party for a month, and the girls say I am almost sure to be chosen Queen."—"But Nancy has anticipated it as much as you," while Dolly hummed,

"I'm to be Queen of the May, mother,
I'm to be Queen of the May."

"Nobody would select a red-headed Queen," said Maud, glancing at her sister's ruddy locks. "Miss Felter's artist nephew from the city is here, and if he likes the tableau, she says he may put us all in a great picture. You would like to see me painted as the May Queen, wouldn't you mother?"—"I am not very anxious," but Mrs. Dayton could not refrain from smiling at her daughter's earnestness.—"Couldn't I take the children over to grandma's?" asked Nancy.—"No, dear; a note from her says she is in her room with another attack of rheumatism."—"Then perhaps I had better stay," sighed Nancy.—"Settle it between you," said Mrs. Dayton and hurried away.—"I don't want to be selfish, and it's my turn," said Maud with a sob, as she began slowly to take off her pink ribbons.—"No, indeed," cried Nancy. "I am the one to stay. As you say, no one would think of me and my red head for Queen; and I shall be much happier thinking you are wearing the pretty crown."—But she wiped away a tear, as she had often done before, over her bright locks which everyone seemed to consider so ugly.—"Oh, Nancy, do you mean it! you are a darling," said Maud, throwing her arms around her neck. "And if you will take my place to-day, you may go everywhere else all summer."—"Of course I will."—So, ten minutes later, Maud went off beaming to the fête, leaving Nancy sitting rather disconsolate on the vine-covered porch.—"Poor Nanny, 'touldn't do to party," chirped Dot, slipping her fat little hand into her sister's. "Dot so sorry."—"Never mind, we'll have a May-party," said Nancy, springing up cheerfully, for she was a light-hearted little creature. "We'll take our lunch up to the grove."—This delighted the 'youngsters,' who shouted with glee, and quietly robbed the garden of every bud and blossom, that had ventured out so early in the season; while Nancy ran across the way and invited Dan, Molly, and Pete Berry; three poor little children, who rarely had any good times, and had never been to a party in their lives. "It will be much better than sulking in the house all day," she thought.—"It was a thousand times better, and a very happy little procession half an hour later wended its way with many a hop, skip, and a jump, to the shady green wood back of the farm.—Nancy, still wearing her white dress and blue sash; Dan making quite a gallant looking prince, in a scarlet cape with a long white feather in his ragged straw hat; Dolly and Dot as maids of honor, bearing the flowers; and Molly and sturdy little Peter straggling on behind with the basket of lunch hastily packed.

"Here is the very spot," called Nancy, at a picturesque little dell, shaded by grand old forest trees, with a mossy mound in the center.—"It was a new experience to the little Berrys, and they were wild with delight.—"I think elves and brownies must live here," said Nancy, as they spread the cloth on the soft grass. "I wish one would appear, and grant me a wish."—"What would it be?" asked Molly, looking longingly at the pile of sandwiches.—"A nice new focking-chair for mother. Her's was broken to-day, and she can't afford to buy another now. She'll miss it so much. But lunch is ready, blow your horn Peter, and call the May fairies together."—Lustily Peter tooted on

TAKING IT EASY.

Drawn and Engraved for the American Agriculturist.

ing on the blanket beside the absorbed reader, who had spent many a Saturday afternoon upon their wardrobes.—"No, indeed, you would ruin their clothes," and Kittie angrily threw one arm over Angelina, the puppet in pink. "Do run away, Daisy, till I finish this story. What a bother you are!"—"But mamma told you to amoose me, and I isn't a bozzer," sobbed the sad-hearted child as she trotted sadly off to investigate a mouse hole with an antiquated tooth-brush.

It was very pleasant in the old attic, with the perfume of fruit blossoms wafting through the open windows; but Kittie ill moved uneasily and brushed back her hair with an impatient gesture, as her mother's parting words came to her mind. "Now, daughter, I shall trust you to take good care of Daisy, while I am away; and try and amuse and make her happy." But Kittie was languid, and her story book was so interesting! She would go in a minute, but first must just see how the story would come out, and so read on regardless of the little sister who was now unusually quiet.—The flies buzzed drowsily, the dolls stared unblinkingly at the spiders overhead, and still Kittie never moved until through with the book, when she started to her feet, with the uncomfortable sensation of having forgotten her charge completely.—But where was Daisy? Not in the hammock or the swing, or in the play-house, behind the timber, for Kittie hunted everywhere. She could not have gone down stairs as she could not lift the trap door. The frightened girl noticed the absence of

Kittie's penitent tale of the proposed flight. For the older sister it was a lesson never to be forgotten.

An Amateur May-Party.

BY AGNES (CARR) SAGE.

Brightly shone the sun, and sweetly sang the birds, and the crisp white muslins, and blue and pink ribbons laid out on the bed, looked fresh and pretty, as Maud Dayton brushed out her straight bangs, and Nancy her curly ones. It was a warm spring day, so unusual on the first of May, and they were dressing for the May-day fête, given to the Sunday-School by kind Miss Dorothy Felter, in the beautiful grounds around her old fashioned white house, on the bank of the river.—"There is to be a throne built for the queen!" said Maud.—"And a May-pole!" said Nancy; "pink, white, and brown ice-cream;" "gold and silver mottoes with fancy caps in them!" "loads and loads of biscuits and cake;" "croquet and tennis on the lawn!"—Thus the happy maidens went on recounting the anticipated delights, to the wondering ears of little Dolly and Dot, who stood by listening with rapt attention.—"I wish the little ones could go too," said Nancy, giving chubby Dot a hug.—"They would only be in the way," responded Maud, "and we couldn't take care of them."

"I wonder what mother will do all day without us, the house all in confusion, and she busy packing up—two cart-loads gone already."—The Day-

the cow's horn hanging at his side. The children were soon enjoying the bread and meat, strawberry tarts, and fresh milk which Mrs. Dayton had left in the closet for her little flock. Nothing cared they for the ants and spiders that scudded across the cloth; but all was fun and merry cheer, and I doubt if the grand fête at Felter House was more jolly than this little amateur May-party in Fairy Dell.—“You, Naney, must be our Queen,” said all the children as they finished the last cake, and threw the crumbs to the birds.—“What! with my ‘brick-top?’” and she laughingly shook her tawny mane.—“Yes, yes,” and they dragged her toward the green throne, sprinkled over with bright spring blossoms, and placed a wreath of violets and snowdrops on her head. Dan and Peter then set up the May Pole, of a rough birch branch, wreathed with common flowers, but which the children considered beautiful. Then joining hands, all danced around, gaily singing a little song they had learned at school, slightly changed for this occasion:

“Hail! Nancy, Queen of May,
On this bright festal day!
Sweet flowers we'll bring,
Gay blossoms of spring,
To crown our Queen of May.”

And a charming picture they made, this little rural court gathered about the sylvan throne, Prince Dan doffing his hat, with its sweeping plume, and chubby little maids of honor, kneeling on each side of their bright-faced Queen, who graciously extended her white hand for each to kiss.

And some one must have been admiring it, for, the quaint little ceremony ended, they were about to disperse for a game of romps when they were startled by a voice, “Stop! don't move!” and a young man in knickerbockers sprang suddenly from a bushy clump. “The court of the flower fays, I see!” he said pleasantly, politely removing his cap. “Pardou meif I have disturbed you, but you have no idea what a pretty tableau you made.” The frightened little ones would have run away, but Nancy said, “Oh, sir, we were only having a little May-party among ourselves. If you want to see a real one, you must go down to the village.”—“I should see nothing that would please me half so well as this; and if I have your majesty's gracious permission I would like to make a sketch of you and your court.”—“Are you Miss Dorothy's nephew, the artist?” asked Nancy in surprise.—“The same. And so you have heard of me. Well! see; I'll give you this if you'll sit just as you are, one hour,” and he held up a shining gold piece. Nancy gladly consented, and the little folk being bribed with sugar plums from the artist's capacious pocket, kept tolerably quiet, while the young man worked busily with palette, canvas and brush. At the end of an hour they were eager to be off.—“Give me another hour, fair May Queen,” begged the artist, and she sat for him alone, while the children scattered though the wood.—“Another,” he then implored, and not until the sun was red and low did he seem satisfied, then dropping three golden dollars into Nancy's lap, he held up the roughly finished sketch.—“Yes, it's me, sure enough!” said Nancy, slowly.—“pug nose, carrot locks, and all! But oh! couldn't you paint it black, like Maud's?”—“What?” asked the artist.—“My—my hair!” stammered Nancy, blushing, “it is so, so homely.”—“Why, child, you're dreaming! Your hair is a glory! the real Titian red, that is so rare. 'Tis the beauty of the whole picture! I wouldn't care to paint it, had it been black.”—Never was there a more perfect surprise. Was it possible that her despised hair, which every one teased her about, could win such praise! She gazed in mute astonishment at the young man as he lay back on the grass, and laughed aloud. “Am I the first to tell you of your greatest beauty!” he said, “the glorious hair, admired by the old masters! Well, go home and let the good country people know what red locks are worth.”—“Mother will know, when she sits in that new rocking-chair,” thought Nancy, as she tightly clasped the three gold pieces, and summoned her little company to their pleasant homeward walk.

She found Maud there before her, looking tired and cross. “You did not lose much,” she said, “for is was stupid from beginning to end. Carrie Green was the Queen after all, while I was only a maid of honor. The artist never came, and I did not enjoy it at all.”—“I am very sorry,” said Mrs. Dayton, who entered in time to hear her daughter's words, “though I think the fault must have been in yourself, for I just met the Browns and they told me the whole fête was delightful. But how is it Nancy looks so bright?”—“Oh! I have had a lovely day,” she said, and little Dolly and Dot shouted, “We have, too! we have, too!” Then she told about their impromptu May-party and the picture. “And queerest of all, mamma,” she ended up with, “he liked my red hair, and really said it was beautiful.”—“Artists see with clearer eyes than we do; but I do not wonder at his choice to-day,” said Mrs. Dayton as she kissed the sweet rosy face, and led the way to the supper table.—The next week they moved into their new house, which was quite in order by May tenth, Mrs. Dayton's birthday. They celebrated it by a pleasant little house-warming.

The only gift mother received was a cozy, comfortable little rocking-chair, purchased with the “May Queen money,” as Nancy called it. Mrs. Dayton declared it a great improvement on the old one she had sadly missed. When autumn came the most admired picture on the Academy walls in New York was one entitled “An Amateur May-Party,” in which was represented a bare-footed little urchin, disguised in a scarlet cape, doffing his hat before a fair little May Queen, with a sweet “flower face,” shadowed by a mass of golden hair.

The Doctor's Talks.

The story that especially interested me when I was a youngster was called “Eyes and No Eyes.” I don't recollect who wrote it, or should I know where to find it now. It told of two brothers, who, having to go on an errand some distance from home, each took a slightly different route. When they returned they gave an account of themselves. One boy came home hot, dusty and tired; he had been annoyed by gnats, been chased by a wasp, and the way was so long and dull that he had a miserable time. The other boy had found the walk short, there was so much to see. He had watched a bird build its nest; saw a squirrel and knew where its hole was, and the insects and their ways gave him so much to look at and the time passed so rapidly that he was surprised when he found he was at his journey's end. There are just such boys now. If there is one thing that I have especially tried to teach you in my “Talks” it is to “use your eyes.” There are some grown people who find life in the country very dull, “nothing going on,” “no excitement,” “nothing to see.” I hope none of our young people think so. “Life in the country dull!” I don't see how it can be to any boy or girl who has

THE PROPER OUTFIT FOR THE COUNTRY.

“What is this outfit?” It is very valuable, indeed if lost no money will buy another. It consists of two parts, a good pair of eyes, and knowing how to use them. Many who have eyes are practically blind. They walk about every day, among the most wonderful things, and are like the boy in the story who had only seen the road-dust and the gnats. I once heard some one speak to Agassiz

about the great labor attending some of his observations. “Ob,” said the great naturalist, “it is all there, and I have only to look and see it, zat is all.” Natural objects do not, like some people, show everything on the surface; there are very few that will not exhibit something more upon close examination. The Barberry bush grows wild in many places, and I suppose that most of you know it. Late this month, or early next, its slender clusters of yellow flowers

will be hanging from the branches. Examine one of these little flowers. If you look into it, it will appear as in figure 1, which is much larger than real. You see that there is a thing in the center, and six little narrow affairs, with knobs at their ends, lay around, with their ends pointing towards the edges of the flower. Now take a fine sliver, a bit of broom straw, or even a pin, and gently touch one of these six knobbed affairs near its lower part and see what happens. Up it jumps, and stands erect! Each one will do the same. Some of the older among you will recollect that in some former Talk I told you about other flowers, and that the central portion was the pistil, that it would ripen into a fruit with seeds, but not before it was touched with a fine dust, called pollen. That this pollen was furnished by the stamens—those six affairs whose quiet you disturbed—not by the whole stamen, but by the knob, or swollen portion, at the end, called an anther. These stamens rise up, touch the pistil in the centre of the flower and give it some pollen.

WHAT MAKES IT MOVE AS IF ALIVE?

It is alive: all plants are alive, only all do not show it by a quick movement, as this does. We do not know just why this moves. My object was not so much to talk about this motion as to show you that even this little barberry flower was worth looking at.

Fig. 2.—FLOWER CLUSTER OF THE DOGWOOD.

THE FLOWERING DOGWOOD

will soon be in bloom—a tall shrub which is often a mass of white. It is quite common, more so than the Barberry in States further West. If I were to ask “Do you know it?” very likely you would say: “Oh yes, very well; a fine tall bush with great white flowers.” Were I to reply: “No doubt you know the Flowering Dogwood very well; but its flowers are neither ‘great’ nor ‘white,’” you would be puzzled and might offer to send me a specimen to show you were right. To save you that trouble I have an engraving at hand (figure 2) which will allow you to see your mistake. The real flowers are in a cluster in the center, a dozen or so, small,

greenish-yellow, and four petalled. But "what are these four large white showy petals?" They are not petals, for those you know belong to the flower, though they are petal-like. Each one is a bract, a peculiar form of a leaf; all together they form an involucre. "What is its use?" One use is this: the flower-buds of the shrub are formed the summer before, and in the fall you may see them, like little caskets, holding the tiny buds of the real flowers, which are closely wrapped up in this involucre, one use of which seems to be to protect the real flower buds during the winter. Later, when open they may be of use to the flowers in some way, which we do not yet know. I have thus shown you that here are two

VERY COMMON PLANTS WORTH EXAMINING, and you will meet with such on every hand—not plants only, but insects, even the most destructive, have a story to tell as have animals of all kinds; and the rocks often are the records of the world's early history. With a good pair of eyes, and the wish to use them, the country need never be dull, thinks

THE DOCTOR.

About the Weed Lists.

When I offered prizes for the longest lists of the weeds found on your farms, I had no idea of the great amount of labor it would require in order to decide upon the prizes. I do not mind the labor, though I do regret that it has made an earlier decision impossible. The lists were made out in various forms. Some were in columns and numbered; in others the weeds were classed alphabetically, and in a few they were arranged according to their botanical families. In some lists the names ran on one after another, making counting very difficult. Some lists were in pencil, and others in red ink, though the majority were properly written in black ink. With five hundred and eighteen of these lists to examine, you may imagine that it was a time-taking job. I had a friend to help me, and it took us two days and one evening to open, count and record the different lists. After this was done, we found that there were ninety-five lists, with over one hundred names in each, some with over two hundred names. As the longest lists would be found among these, the examination and comparison of these became a slow and difficult work, especially as some lists contain many that cannot be considered weeds, but merely wild plants never found in cultivated grounds. At

the time of writing this, I have not been able to complete the comparison of the ninety-five lists, but will give the result in another part of the paper, which is printed later. I would thank all those who have sent lists, even the smallest; my only regret is, that I cannot give a prize to every one. Whenever I have offered a prize to be competed for, I have almost regretted having done so, at the thought of the many who must be disappointed. When you take part in a competition of this kind, you should not set your hopes too strongly on winning. In the case of the weed lists, the looking after the weeds, learning the names and recording them, has been useful, even if the large amount of labor did not bring a prize. "THE DOCTOR."

Our Hen and Quails.—Little Girl's Letter.

Our hen we call Minnie. She is very much like some girls I know. If they have a problem in arithmetic, they always get some one else to work it out for them. If they want a pair of mittens to wear to school, they always manage to have somebody else knit them as a present. Our hen has the same knack of doing things. We never knew her to make a nest for herself, but she always deposits her eggs in some other hen's nest; and we suppose it was in this way she got her little quails. We missed her for about two weeks and were afraid something had caught her, when one day what should we see but Minnie coming through the yard with eleven little quails, the proudest mother any one ever saw!

We were all delighted to see her alive, and with so many funny chickens. Well, Minnie, with her constant, watchful care, raised them all. When almost grown, mamma had a quilting, and a house full of ladies came. When they were all seated around the dinner table, something frightened the quails, and what do you think they did? Why they just rose and flew in and lit right in the middle of the table. And such a confusion, jumping up, running round and screaming among the ladies! They frightened the quails almost to death, poor little things, and they were glad to fly back to their mother, and Minnie was glad to get them close to her. The hen and quails always will fly into the house every time anything frightens them, and we have had many amusing incidents occur in this way. We now have a large flock in the orchard. They will come close to the door and whistle, and are as tame as chickens, because we never allow any one to molest them. LILY WING.

A Boy's Poultry Keeping.

"A. C. S.," Williamsport, Pa., tells us "How I take care of my chickens."—He does not state his age, but we judge from his writing that he is quite young. At any rate, his rules for management are good ones, and were they followed by older persons, they would find it profitable. He says: "First—I feed my fowls every morning and evening. Second—I gather my eggs every evening. Third—I keep the coop clean. Fourth—I don't feed oats. Fifth—I change their food almost every week. Sixth—I have the nests clean. Seventh—I remove all rubbish from the yard. Eighth—I never drive or scare them when laying. Ninth—I do not let them steal their nests. With six fowls, I get two and three eggs a day, and in summer more."

Which is the Top of an Apple?

Every now and then persons have a discussion as to which end of an apple is the top, and as they cannot decide the point, agree to refer it to the *American Agriculturist*. Everyone who has gathered an apple knows that the stem-end is uppermost as the fruit hangs on the tree, and many claim on this account that the stem-end is the top of the apple. If you young people wish to decide this point for yourselves, you must look at the fruit while it is very young, soon after the blossoms fall away. Apple blossoms, how beautiful they are as they cover the trees in such profusion! Besides admiring them in a mass, it will be well for you to examine some of them closely and learn about

THE BEGINNING OF THE APPLE.

You, of course, know that the showy part of the apple blossom is the corolla, it has five petals, or flower leaves (A); outside of these are five narrow, leafy parts, the sepals, which together are the

A CLUSTER OF APPLE BLOSSOMS WITH SECTION OF A FLOWER.

Engraved for the American Agriculturist.

calyx. As you look into the flower you see five slender pistils, and on the edge of the flower-cup a great many stamens. In many flowers you know that these parts are all very distinct and stand upon the top of the flower-stalk, but here they all seem to be upon the top of a very small apple. If you cut the blossom in two lengthwise, you will find it to appear as at B in the engraving. You will see in the centre the lower parts of the pistils, the ovaries, and these are surrounded by the lower part of the calyx, which adheres to them. The tiny green apple at the bottom of the blossom is mainly the enlarged calyx. When the blossoms fall away, there is no difficulty in seeing which is the top of the apple; when it is very young, the stem end is evidently the bottom, and the opposite, or calyx end, is the top. As the young apple grows, it becomes too heavy for the stem to hold it in an upright position, so it soon falls over, and afterwards hangs top-end down. If you cut open a young apple now and then, as the fruit is growing, you will see that the seeds are formed, and that they are being enclosed in tough parchment-like cases. These which you know so well in the core of the ripe apple, are the real fruit, that is, the ripened ovary. They are surrounded by the lower part of the calyx, which is attached to them; this grows very rapidly, and in time ripens to form the great mass of the apple. The portion then, which we eat in the apple is mainly the ripened calyx, and the core, which we throw away, is what in the botanical definition is the true fruit of the apple tree.

ACROSTIC PUZZLE FOR MAY, AND A DECORATION DAY REBUS.—Arrange the letters in each flower in such a way as to make a word; arrange the six words so that the initials will give the name of a flower.—The answer to the Illustrated Rebus is an altered selection from Robert Herrick's Poems.

The Banyan Tree.

One of our young friends asked us: "Is not the Banyan tree the most wonderful tree in the world?" It is a wonderful tree—indeed quite as much so as a stalk of Indian corn. The corn-stalk has the peculiar growth which makes the Banyan celebrated. The Banyan tree is a native of India and other parts of Asia, and is a kind of fig, with fruit as small as a cherry, and not pleasant to eat. The branches produce roots, which at first swing in the air, but on reaching the earth they throw out

could not come into the house to trouble her. Captain John, always in a hurry, soon departed on another long voyage, after fully instructing his brother how to care for the camelopard.

The next day Mr. Dyckman exclaimed while at dinner, "I wish John had left that thing in Africa where it belonged. Why, the beast got out this morning, and just about ruined my young fruit trees by eating off the leaves and branches; and then it got at neighbor McLaren's horse-chestnuts, and when our man Jerry went after it, it gave him such a kick that he'll never go near it again,"—

rowful at the animal's sufferings, felt relieved when it was dead. Though Richard assured his father by his book that "the skin was very valuable," he was hastily buried in the meadow beyond the brook. At the tea table Richard broke in, "the camelopard was so called because it resembles both the camel and panther or pard..." but was interrupted by his father with, "I think I know all I want to about it. If this one should have lived, I should have been bankrupt in a month."—Probably he wrote something of the kind to Captain John, for no more presents of wild animals came to the Dyckman farm.—I will only add for the benefit of superstitious people that despite the broken looking-glass, the camelopard's death has been the only one in the Dyckman family up to this time.

Corals not Insects.

Miss "S. A. W." asks, "If coral insects make so much coral as to form islands, why is coral jewelry so costly?" There are many different kinds of coral, but none of them are built by insects. The "coral insect," which was talked about by the older writers, does not exist. Coral is, however, produced by animals, but of a very low order, budding and branching so much like plants, that they were at one time claimed to be plants rather than animals. They belong to the *Zoophytes* (a word meaning an animal that grows like a plant). Their hodies are very soft, and they surround themselves with a strong covering, much like marble, which they get from the sea water. The corals which form the islands are usually white, and of course are large kinds. Some are rounded and others branching, and when recent they contain the living animal or animals, which put out their feelers from the numerous openings. The coral used for jewelry is a very solid red kind, found mainly in the Mediterranean Sea. It is rarely more than a foot long, and seldom larger than the little finger. The engraving of a branch of this, shows the animals spreading their feelers from the pores in the sides. In the coral fisheries, a kind of drag is used to break off the coral, and bring it into the boats. Some of this is found in the Persian Gulf, and in the Red Sea. The tint in different localities varies from a light-salmon, to rose-pink, and dark-red. A black variety is also found. Naples is the principal place for the manufacture of coral ornaments, and a large number of people find employment in working up the material into necklaces, pins, ear-rings, bracelets, etc. The work done by the coral animals in building up reefs and even large islands, is truly wonderful. Slowly, very

A BANYAN TREE.—Engraved for the American Agriculturist.

smaller roots that become fixed in the ground. These upright roots grow large and become like trunks. The broad tree-top is thus supported by many pillars. Indeed, the original trunk often decays, leaving the top propped up by these root-trunks. Three hundred and fifty of them have been counted on one tree, and a tree is mentioned so large, that its wide top will shade seven thousand persons!

Mr. Dyckman's Camelopard.

The Dyckman family would have lead a happy, peaceful life on their large and valuable farm, but for Uncle "Capt. John's" fondness for birds and animals, which was so great, that on every returning voyage he brought some new, strange creature as a present for Mrs. Dyckman. She, and her neighbors, too, were however saved much annoyance by the usual early death of these unacclimated animals. Once, a monkey persisted in living, and was up to all sorts of tricks, chasing the children, tearing their clothes, frightening the mother when it broke its chain, as it often ingeniously did, until it was sold to a menagerie man. Then quiet reigned for a season; but the Captain soon came with a new pet, a veritable camelopard. Mrs. D. could hardly say "how do you do, Captain John," but he shook her hand in the heartiest manner, lovingly pinched little Johnny's cheek, kissed wee Dora, and tossed the baby almost to the ceiling. The children were wild with delight, and eagerly inquired where the new pet came from.—"Why, from Africa, of course," said Master Richard, grandly, who, inheriting Uncle John's love of animals, had read Wood's Natural History. And he went on reassuringly, "the camelopard or giraffe is very gentle, though sometimes when provoked will kick with his hind legs," looking warningly at little John who was sidling up to the tall pet with a stick in his hand. Mrs. D. was less disturbed on thinking that an animal sixteen feet high

"That's just what the book says. If provoked he will sometimes kick," chimed in Richard, triumphant at this illustration of the truth of his researches.—"But that won't make Jerry feel any better," replied Mr. D.—"And I hope you've tied him fast now," said Mrs. D.—"Oh, yes, as fast as any one can tie a neck so long, that you don't know what part to hitch to that he'll not slip out of somehow."—The children were all delighted, and Richard read from his book, "the flesh of the camelopard is considered quite delicate and tender," when Mr. D. broke in, "we might cook and eat him; what say you, wife?"—She was replying, "I should feel as if eating a horse"; but her voice was drowned by the children's "noes," thinking their father in earnest.—"Why didn't you tell Uncle John you didn't want it?" continued mother.—"Oh, I didn't want to hurt his feelings when he gives us so many nice presents. You must never look a gift camelopard in the mouth," he responded, and the children laughed.

That very afternoon as Mrs. D. sat near her open chamber window, sewing a button on her shoe, the tall pet peered in right under her nose, and throwing the shoe in her fright, she shivered a fine mirror. She had always held the superstitious notion that to break a looking-glass was a bad omen, and she went down stairs weeping, just as Jerry came limping in with, "where's Meester Deekman; sure that haythen haste"—"camelopard or giraffe," chimed in Richard.—"Karmilipard thin! I'm thinking the name and the baste is the match of old Nick. Why jest as I was puttin the pizen green on the pertater vine, he kim over the fence to give me another kick, and I sot the pail in the crook of the apple tree and run away, niver dramin he'd touch it. But he did, and jist come outside and hear him groanin."—It was too true. The camelopard had come all the way from Africa to die like a common potato bug. The children were inconsolable. Mrs. D., though sor-

A BRANCH OF PRECIOUS CORAL.

slowly, by their united labors, the mass is built up. At last a small island appears, and in time plants of some kinds show themselves. "Where do the seeds come from?" Most likely they are brought by the birds. It has been found that water-fowl carry a great many minute seeds from place to place in the mud that adheres to their feet.

OUR RECORD

OF

Recent Agricultural Inventions.

Plow.—J. T. Millen, Thomasville, Georgia, Jan. 22; No. 292,343.—The inventor seeks to avoid the clogging of the brace, which usually supports the plow standard, while bracing the standard thoroughly and preserving the old-fashioned connection of the handles

with the beam. The standard and heel-piece are cast in one, and carry a clip-socket for the shovel. The heel-piece, the beam and the handles are fastened together by the bent braces, *e, e*, which are bolted to the opposite sides of the parts connected so as to support and brace them firmly. The improvement is applicable to any plow having a heel and standard connection for shovel cultivator or mold-board.

Gang-Plow.—H. M. Cormack, Malden, Mass. Jan. 1; No. 291,156.—The figure shows a sectional elevation from front to back through the middle of this improved gang-plow. The improvements claimed consist in certain novel features of construction and arrangement of parts. They relate chiefly to the means em-

ployed for raising and lowering the plows, for adjusting the plows lengthwise along the auxiliary frames, so that the two gangs of plows may be made to turn their furrows in the same or in opposite directions, for regulating the width and depth of the furrow, and for handling the harrow. This plow is intended for use with steam power.

Attachment for Plows.—V. Wood, Peru, Ind. Jan. 22; No. 292,272.—The inventor seeks to improve the construction of harrow attachments to plows, to obtain greater lightness and efficiency. The har has

oblique tooth-sockets, and is attached to the plow standard and the mold-board, so as to have a vertical adjustment. The teeth are independently adjustable, and are held in position by set-screws or otherwise.

Harrow.—A. C. Evans, Springfield, Ohio. Jan. 1; No. 291,174.—By bending the harrow-tooth as shown in

the engraving, Mr. Evans is able to make a reversible harrow, straight-toothed on one side, and inclined-

toothed on the other, of extremely simple construction. The manner of inserting the tooth in the beam, is part of the invention.

Harrow.—S. Shoemaker, Nokomis, Ill. Jan. 1; No. 291,414.—This is a combined harrow and corn-marker. The drag-bars are three-cornered, smooth in

front and toothed behind, and rigidly connected by cross-bars. The teeth of the middle beam are inclined forward, the others backward. The corn-markers are flexibly attached to the middle bar.

Hay-Fork.—Henry Stahl, Cherry Mills, Pa., Jan. 22; No. 292,378.—The construction of this fork is clear-

ly shown in the engravings. The inventor seems to have succeeded in his purpose to make a light, strong, and efficient yet inexpensive fork.

Thrashing Machine.—W. H. & J. Butterworth, Jr., Trenton, N. J., Jan. 29; No. 292,731.—The inventors claim a considerable number of improvements

in the machines known as vibrating thrashers. A section of an improved machine is shown in the engraving; the patented features are of such a nature that a brief description of them is impossible.

Plow.—A. A. Roberts, Quitman, Arkansas. Jan. 1; No. 291,087. The improvement lies in the means for attaching the plow to the frame, which consist

in the combination of the slotted beam *a*, the forked and pivoted cam-lever *c*, and the clamping device *b*, as shown in the engravings. The improvement is specially applicable to cultivator plows.

Dust Exhauster and Conveyor for Thrashing Machines.—David Logan, Harts-town, Pa., Jan. 29, 1884; No. 292,498.—The construction of this device is clearly shown in the engravings, fig. 1

being a perspective view of the casing of a separator with the invention attached, fig. 2, a section of the same. In operation the dust is exhausted from the closet *b*, by the suction of the rotary fan in the fan-chamber *h*, passing through the elastic tubes *o*, and out through the pipes *s* and the conveyor tube, *t*. The direction of the discharge is determined by the direction of the rotation of the fan, and that is governed by the twist of the belt.

Machine for Gathering Insects from Plants.—Ferdinand Wiskocil, Prairie Du Sac, Wis., Jan. 15, 1884; No. 292,083.—This machine is specially adapted for the work of collecting potato beetles. As the machine is propelled the crown-wheel revolves, its cogs engaging a pinion on the fan shaft, causing the fan

to revolve and strike the insects off from the plants into the box, which may contain poison for killing them. The screen prevents the insects from being thrown beyond the box. The wheels and other parts of the machine are adjustable to suit the work in hand—the width of the rows, the height of the plants and so on.

Straw Cutter.—J. N. Slaughtenhaupt, Chambersburg, Pa., Jan. 22; No. 292,263.—This invention

simply adds to the cutting machine previously patented by the same inventor the inclined spout *d*, and its fastenings as shown.

Machine for Sharpening Mowing Machine Knives.—Spencer McCay, Topeka, Kan., Jan. 22, 1884; No. 292,244.—The claims of this patent cover the mode of hanging the grinding wheel *n*, on the swinging frame *m*, so that the wheel can be

moved up and down, and from side to side to follow the bevels of the teeth; together with the means for turning and guiding the wheel, and for rigidly holding the knives to be ground. The engraving shows a plain view of the machine.

Dairymen Getting Rich.

Progressive dairymen who are only satisfied with the best results, are adding to their wealth and conferring a benefit on society, by the rapid improvements they are making in the art of butter making. This class use Wells, Richardson & Co's. Improved Butter Color, and know by actual test that it fills every claim made for it.

DID YOU EVER THINK

THAT using poor Salt for butter and cheese was like using poor thread in making up good material into a garment. The difference in cost between using the best and the poorest Salt amounts to less than 1-30th of a cent per pound on butter, and 1-60th of a cent on cheese, and we have seen it make a difference of three cents per pound in quality.

When Higgin's Eureka Salt was first introduced many people naturally desired to wait and see results. In seven years it has carried off nearly all the honors, and it is now generally admitted that it compares with other Salt as refined sugar compares with raw sugar, and the Higgin process in Salt manufacture was as great an advance as the Bessemer process was in making steel.

IT ADDS MILLIONS EACH YEAR to the value of American dairy products, and the following figures show that this is appreciated by American butter and cheese makers who do not believe in the principle of using poor thread to make up good material.

IMPORTS OF HIGGIN'S "EUREKA" SALT FOR EIGHT YEARS.

De Menil, now in its fifteenth year, is brilliantly illustrated, purely Western in make-up, replete with stories, poems, timely reading and humor, \$1.50 a year. Sample copy and a set of gold colored picture cards sent for ten cents. Address, A. J. GILMORE, 213 North Eighth Street, St. Louis. THE AMERICAN AGRICULTURIST and ST. LOUIS MAGAZINE, sent one year for \$1.75.

A NEW WATER-MELON—AMERICAN CHAMPION FIFTY DOLLARS IN PREMIUMS.

WATER-MELON—AMERICAN CHAMPION.
largest; and \$10.00 to the grower of the third largest.

For full particulars see our Illustrated List of Novelties, mailed free to all.

With this superb new Water-melon we take pleasure in introducing to the public a variety which, we are confident, possesses qualities superior to any kind hitherto cultivated.

It is a cross between *Rattle-snake* and *Scaly-bark* Melons, both renowned for their excellence. In general character it partakes somewhat of the features of each, but excels in all the most desirable qualities of a first-class Melon for market as well as home use.

To test its market value, last summer, some of these Melons were sent to leading Melon dealers in the principal cities in different parts of the country, and although at the time the markets were overstocked with other varieties, these sold readily at from \$5 to \$10 per hundred more than current prices. The following are some of the comments of the parties who sold them:

"They created more commotion in the market than was ever known in the Melon trade."

"In shipping quality they surpass all varieties known in the market."

"They carry splendidly; the specks, rots, and breaks are much below the average."

"In keeping quality there is no other kind to approach it."

"Although the market was very dull, these were engaged several days ahead, at advanced prices."

After hearing these endorsements from men who are first authorities in the fruit trade, it will be evident to every one that no other variety combines so many valuable qualities as the *American Champion*.
Price, 25 cents per packet; 5 packets for \$1.00.

FIFTY DOLLARS IN PREMIUMS,

To be awarded as follows:—\$25.00 to the grower of the largest *American Champion Water-melon*; \$15.00 to the grower of the second largest; and \$10.00 to the grower of the third largest.

A REAL LUXURY.

BLISS'S AMERICAN WONDER PEA.

Extra early—requires no bushing—exquisite flavor.

After a more extended trial than any previous introduction was ever subjected to, *Bliss's American Wonder Pea* has been pronounced by press and public the most desirable wrinkled variety in cultivation, while, in point of quality, the best horticultural judges in the world maintain that it is surpassed by no other variety.

CAUTION.—Each succeeding season the necessity becomes greater of cautioning the public against spurious *American Wonder* peas. We have on different occasions secured several packets from dealers who claimed to supply the genuine *Bliss's American Wonder Pea*, which, upon trial, proved to be entirely unlike it. We are within the mark, when we say, hundreds of bushels other than the genuine variety have been sold. As there seems to be no protection from such fraud, it is to your interest to procure a supply from head-quarters; for unless you obtain the *Genuine Bliss's American Wonder*, you will never know why it is that, wherever grown, it has been pronounced by all the earliest, the most productive, and best-flavored variety in cultivation.

Per pkt., 10 cents; pint, 40; quart, 75, by mail, post-paid. When delivered at our store, or sent by express at purchaser's expense: pint, 30 cents; quart, 50; peck, \$2.50; bushel, \$8.00. Prices for larger quantities on application.

From *Rev. Henry Ward Beecher*.—"Your peas are wonderful, none others so good. I do not mean to plant another year any others, early or late. They beat the Alpha in earliness, and out of sight in flavor."

From *Hon. Marshall P. Wilder, Pres. American Pomological Society, Ex-Pres. U. S. Agricultural Society*.—"My *American Wonder* is a wonder, equal in sweetness and richness to the *Champion* of England, which is all that could be desired."

STERLING NOVELTIES OF RARE MERIT.

New Flower Seeds, New Vegetable Seeds, New Cereals, New Potatoes, New Seeds for the Farm, New Strawberries, New Raspberries, New Currants, New Blackberries, New Grapes, New and Rare Plants for the Garden and Conservatory, etc., etc.

NEW VEGETABLES A SPECIALTY.

My Vegetable and Flower Seed Catalogue for 1884 will be sent FREE to all who apply. Customers of last season need not write for it. All seed sent from my establishment warranted to be both fresh and true to name, so far, that should it prove otherwise, I agree to refill the order gratis. My collection of vegetable seed is the most extensive to be found in any American catalogue, and a large part of it is of my own growing. As the original introducer of *Eclipse Beet*, *Early Ohio* and *Burbank Potatoes*, *Marblehead Early Corn*, the *Hubbard Squash*, *Marblehead Cabbage*, and a score of other new Vegetables, I invite the patronage of the public. In the gardens and on the farms of those who plant my seed will be found my best advertisement.

JAMES J. H. GREGORY, Marblehead, Mass.

Great Northern and Southern Nurseries.

H. W. JOHNS' ASBESTOS LIQUID PAINTS

Our liquid paints are composed exclusively of the best and purest materials combined on different principles from any other Liquid or Mixed Paints. They have been thoroughly tested in nearly all parts of the world, and have been found to withstand the severest tests of climatic changes, sea-air, and other trying exposures where the best white lead has failed, and the universal testimony of those who have used them is sufficient proof of our claims that they are in every respect strictly reliable and first-class paints of a higher grade than have ever before been offered to the public for structural purposes, either in "paste" or liquid form, and second to none in richness and permanency of color, beauty of finish, durability, uniformity, and all characteristics which are requisite to form a perfect ornamental protective covering.

None but the purest linseed oil and the best pigments known enter into the composition of these paints, and they contain no water, alkalies, benzine, or other deleterious or useless adulterations; we do not, therefore, compete in prices with the cheap paints with which the market is flooded, and which are composed largely of water and other inexpensive ingredients.

Our paints are sold by U. S. Standard Gallon measure (231 cubic inches); i. e., our packages contain from 8 to 12 per cent. more paint than is usually sold for the same quantity, and they weigh from 10 to 20 per cent. more to the gallon than any others in the market. ONE GALLON WILL COVER FROM 225 TO 250 SQUARE FEET, TWO COATS.

We manufacture forty eight shades of "body" and trimming colors, and also make Standard and Light Greens, Light and Dark Blues, Reds, Black, etc.; samples of which will be supplied on application.

We will send free by mail our pamphlet

"STRUCTURAL DECORATION,"

containing views of many prominent buildings and other structures on which these paints have been used and the colors employed, and which will assist consumers in selecting shades and colors for the satisfactory decoration of their buildings.

WHAT PRACTICAL PAINTERS

and others say:—

Portsmouth, N. H., Dec. 9, 1880.

Gentlemen: Enclosed find check for settlement of our account in full. We here desire to express our entire satisfaction with all the goods received from your house, they being in every particular up to the standard, both as to your claims and our requirements.
W. J. SAMPSON,
House, Ship, and Ornamental Painters.

Cohocton, N. Y., May 24, 1882.

Dear Sirs: The Paint came to hand, and my painter says it is the best he ever saw—spreads very fine; one coat completely covers all traces of the wood, and equals two coats of other kinds.
Please send the following as before: **
Yours truly,
THOMAS WARNER.

Friars Point, Miss., June 6, 1879.

Dear Sir: Three or four years ago I purchased a barrel of your Asbestos Paint, with which I covered a store-house. The result has been satisfactory. I am now building a house more than ordinarily costly for this locality, and would like you to snip me one barrel, 40 or 50 gallons, as per shipping directions enclosed. Yours, etc.,
J. L. ALCORN,
(United States Senator).

Auburn, N. Y., March 1, 1878.

Dear Sirs: In answer to your inquiry as to how we like your Paint, we are more than entirely satisfied with it. We are large users of paint, and of all that we have ever used are satisfied yours is far superior; it is put on with less labor, covers better, flows more easily, has a better body, and, as far as our experience goes, will stand the weather better than any other paint we know of. Your Roof Paint is unsurpassed. We used one coat on a tin roof, and to-day it looks as fresh and the color is as bright as when first applied. Respectfully yours,
JOSHUA BARBER & SONS,
Manufacturers of Woolen Goods and Carpetings.

Andes, N. Y., Nov. 23, 1882.

Dear Sirs: I have had a thorough knowledge of the "Asbestos" paints for a number of years from actual experience, and I do not hesitate to say that I deem it to be the best article for either inside or outside work that is now offered to the public. The covering quality of the Asbestos Paint is truly surprising. The tints are especially fine.
Truly yours,
JOHN G. DEAN,
Practical Painter, Grainer and Decorator.

Mechanics Falls, Me., Jan. 3, 1881.

Gentlemen: Please send us bottom prices for the Asbestos Liquid Paints. ** We can only say, the Asbestos Paints have given us and our customers perfect satisfaction. ** In a word, we like the Asbestos Paints the best of any Liquid Paints we have ever sold or used.
Faithfully yours,
HAWKES & WHITNEY.

435 East Houston street, New York,

Gentlemen: ** We can recommend your paint to any one as being first class, as the exterior of the Oriental Hotel, Manhattan Beach, will show, it having stood the storms of last winter, and looking as well to-day as the day we finished it. Yours truly,
G. C. LUGAR,
House and Ornamental Painter.

Fulton, N. Y., April 5, 1880.

Dear Sirs: Enclosed find check to balance account. I shall use your Paint more extensively this year than last, as every one who has had it put on, likes it better than Lead and Oil. I have finished painting my own house with your Paint, which I would not have done, did I not consider it better than lead. Yours truly,
MARCUS F. CRAHAN, House Painter.

ROOF, CAR, AND BRIDGE PAINTS.

These Paints possess a more elastic body than any other, and are less liable to injury. They are prepared ready for use, and have proven to be the most economical paints ever produced for similar purposes. They were originally designed for preserving TIN and OTHER ROOFS, but are now also used for Railroad Buildings, Bridges, Freight Cars, Steamboat Decks, Boats, and all wood and iron work exposed to salt or fresh water, and are especially adapted for Out-Buildings, Fences, Floors, Gas-Holders and other iron and rough wood-work. They are supplied in seven colors, viz., Brown, Red, Yellow, Gray, Buff, Slate, and Cream-White. One gallon will cover about 400 square feet, one coat.

ASBESTOS ROOFING.

The only reliable portable Composition Roofing in use. It is suitable for steep and flat roofs in every climate, and has been in use for a sufficient length of time to warrant us in claiming it to be the best and most economical substitute for tin.
It can be easily applied without the aid of skilled labor.

RELATING TO ROOFING.

Oswego Starch Factory,

Oswego, N. Y., Oct. 28, 1878.

H. W. Johns, 87 Maiden Lane, New York:
Dear Sir: We have several acres of your Asbestos Roofing on our buildings; the first roof, put on fifteen years ago, is in good condition, and we prefer it to any other.
Yours respectfully,
T. KINGSFORD & SON.

Office Bigelow Blue Stone Company,

247 Broadway, New York, April 8, 1880.

Gents: Owing to the fire which occurred on the morning of February 1st at the works of our blue stone and planing mills, situated at Malden on the Hudson, we shall shortly require more of your roofing material. That portion of the building covered with shingles was entirely consumed, but we take pleasure in stating that when the flames reached the part covered with your Asbestos Roofing, the edges fell over that part of the roof and prevented further progress of the flames. The building would have been a total loss had it not been for your roofing.
You are at liberty to make any use you choose of this

letter, and refer any one to us as to the merits of the Asbestos Roofing. Respectfully yours,

JOHN MAXWELL, Lessee.

Office of Passaic Zinc Co.,

113 Liberty street, New York, April 5, 1875.

Dear Sir: We have had your Asbestos Roofing in use at our zinc works for some four or five years, and prefer it to either tin, slate, or any other kind of covering for roofs.
Yours respectfully,
MANNING & SQUIER, Agts.

South Bend Iron Works,

Proprietors of Oliver Chilled Plow Works,

South Bend, Ind., Dec. 12, 1881.

Gentlemen: Replying to your favor of the 9th inst., our experience with the Asbestos Roofing is very satisfactory. We have used nothing else for the past two years, and design continuing its use on the new buildings to be erected by us the coming spring. The economy and durability of your Roofing is beyond question, and we are glad to be able to give it our endorsement.
Yours truly,
SOUTH BEND IRON WORKS.

ASBESTOS BUILDING FELT.

For interlining Frame Buildings. Is strictly fire, dust, and wind proof, and is rapidly taking the place of the ordinary sheathing felts.

ASBESTOS PLASTIC STOVE LINING,

a durable and economical Lining for Stoves, Grates, Ranges, and Furnaces, and for Repairing Stove and Flue Joints, Fire-brick, etc., etc. Easily applied with a trowel, will not burn out, and clinkers will not attach to it.

We also manufacture, ASBESTOS STEAM-PIPE and BOILER COVERINGS, ASBESTOS PISTON and WICK PACKING, ASBESTOS MILLBOARD, ASBESTOS SHEATHING, ASBESTOS FIRE-PROOF PAINT, COATINGS AND CEMENTS, ASBESTOS CLOTH, THREAD, YARN, TWINE, CORD, ETC., ETC.

H. W. JOHNS MANUFACTURING CO.,

87 MAIDEN LANE, NEW YORK.

170 North Fourth street, Philadelphia.

45 Franklin street, Chicago.

FULL DESCRIPTIVE CATALOGUE SENT FREE BY MAIL.

"The Village Blacksmith."

It is a long time since we have had a good old-fashioned medical humbug, like Old Mother Noble's or Eddie Eastman's, for example; a marvellous remedy, with a story telling of its almost miraculous discovery. After a dearth of new remedies, or rather of their literature, a new one with a new story is, in its way, refreshing. The latest story is that of the "Village Blacksmith," and we have his portrait. Were it not that there is an anvil and a hammer, and the label that he is a blacksmith, we should take it to be the portrait of a prize-fighter dressed in his good clothes. The blacksmith's name was Gardner, and he lived in Yorkshire, England, he was a very good man; he had a daughter; she married and became Mrs. Cole and went to London to live. Cole was thrown out of work, went to India and was soon killed on a railroad. About this time the bellows did not blow in the smithy, nor did the hammer ring upon the anvil, for the blacksmith was sick, had gone into a decline, and could not work. Matters looked very gloomy for Mrs. Cole, her husband dead and her father so sick, that she daily expected to hear of his death. When matters were at their worst, she was surprised to receive a letter from her father, who told that he was getting well and how it happened. In his illness he was, on warm days, carried to a place overlooking the sea. One day, while there, in one of his paroxysms of pain, the blacksmith clutched at a bush, and not thinking, chewed the little stems. That did for Gardner; in less than an hour his pain was relieved, his doctor being a sensible man, told him to "continue the drops." A wonderful shrub it was, for every time Gardner took its juice, he felt "new life springing into his veins."

THE USUAL RESULT FOLLOWED.

The stuff was made into pills, because it would do "a vast amount of good." Mrs. Cole sold the pills, because she felt it was her "duty." The pills were called "Globe Pills," not because they were globular in form, but because they would have "a world-wide reputation." The rest of the pamphlet is devoted to relating various cases in which the pills have performed wonderful cures. If one doubts it, there is Mrs. Cole's portrait, as well as that of her father. These pills have been introduced into this country. Of course, they will have their brief day, and then join the hundreds of other "certain cures" in the limbo of quackery.

Lotteries, Royal and Other.

J. Goldsmith & Co., St. Stephen, New Brunswick, have had a monopoly of the "Royal" lottery business for a long time, though they call it a "Royal Distribution" of Cash Gifts. Now comes another "Royal" affair with its headquarters at Merriton, Canada. It is to the credit of this that it does not try to conceal its real character by calling it a "distribution," but plainly declares itself to be a "Lottery," and a "Royal Canadian" one at that. It does not sneak behind "gifts," but has "prizes," and will have a "drawing" at a given date, without any of the fool-cry of a "distribution."

PAYING THE BILL POSTERS.

This "Royal Canadian Lottery" sends out its announcements, or show bills, to people in our Western States, requesting them to post these "in a conspicuous place." To pay for this service, the poster is to secure "one whole ticket of the said Lottery" by registered letter—provided he sends "one twenty-five cent silver-piece."—This shows remarkable shrewdness on the part of the Royal Lottery. This concern evidently has an agency in the Republic, as its envelopes containing circulars, etc., bear the New York post-mark. Our Post-Office officials should look out for this.

THE LAWS NEED AMENDING.

While the present laws have done much to break up lotteries by excluding their correspondence from the mails, these Canada chaps disregard them. An amendment was presented early in the present session of Congress which contained a most important feature. It proposed to exclude from the mails all newspapers containing advertisements of lotteries. Should this pass, it will be the most telling blow yet dealt the lottery

managers. The necessity for thus excluding such papers is shown by the fact that lotteries are now advertised almost as freely as ever. Not only in papers with a large circulation, but in small local sheets, through which the managers reach the rural population. An Ulster County, N. Y., paper, advertises a Kentucky lottery with a tempting display of prizes. The publishers of the paper do not seem to be aware that they are inciting their readers to violate the spirit, if not the letter of the laws of their own State and those of the Union.

Tree Peddlers and Agents.

"Hawkeye," Peru, Iowa, asks us to give warning that a very "toney" agent is abroad, offering and taking orders for, among other improbable things, "The only true Grape Vine Raspberry." The warning comes too late to be of much use this season, but if our readers have heeded our frequent general caution, to let all these heretofore-unheard-of trees and plants alone, they will have escaped this among other swindles. This "Grape-vine Raspberry," turns up anew like the return of an old friend, after an absence of many years. While we can not be sure what this particular "Grape-vine Raspberry" really is without seeing the plant, it is likely to be identical with that sent under the same name several years ago—the Purple Flowering Raspberry (*Rubus odoratus*). This shrub is not rare in rocky places throughout the Northern States, and with its rose-purple flowers, two inches across, is very ornamental. Its very flat, dry fruit, is well nigh worthless, and is produced very sparingly. We repeat, that no really valuable new fruit is ever first introduced by peddlers. If one of these claims to have exclusive sale of a new tree or plant, or claims that this is introduced for the first season, our readers may be sure that it is just the tree or plant that they do not want.

Small Seed Swindles.

Every now and then a person having what he considers a valuable variety of vegetable or other plants, offers to send the seeds to those who will pay postage upon them. Editors, thinking that they are doing a good thing, make the announcement gratuitously. When these offers are made in good faith, those who make them usually soon run short of seed, and much dissatisfaction results. But such offers are not always disinterested: A. G. Rees, Nemaha Co., Kans., writes us that he saw an advertisement of one who offered to send a packet of a new variety of corn, upon the receipt of five cents. Mr. R. sent his half time, and received "thirty-eight kernels of mixed corn," of these only seventeen grains came up. From these seventeen stalks only seven badly filled ears were harvested, of an impure or mixed variety. This is a rather small swindle, but Mr. R. thinks, if one had enough to do, after paying for the thirty-eight grains, and the postage, the sender would make a handsome profit in this small seed business.

Coloring Photographs.

Inquiries and some complaints continue to come with reference to those parties who offer large inducements for ladies to work for them at coloring photographs. The number of these concerns is on the increase, and in addition to those named some months ago, a "Royal" and a "Reliable Manufacturing Co." are offering inducements. A curious thing about the whole matter is, that each one warns the public against all others. Now a firm in Iowa, claim to be the "original inventors, and the only reliable establishment." We shall be glad to hear from those of our lady readers, who have had any experience with this photograph business.

Cautionary Signals.

A Preserving Recipe.

A subscriber in Augusta, Ga., writes us that the following recipe is selling in that city for two dollars. It is claimed to preserve meats, fish, fruits and vegetables, in a perfectly natural state for thirty months. Here is the recipe: "FOR FIVE GALLONS.

Boracic Acid, 2 oz.
Carbonate of Soda, 2 oz.
Salicylic Acid, 2 oz.
White Sugar, 2 lbs.,

mix the first three ingredients in a quart of cold water, stir until all is dissolved, then add the sugar. Pour this mixture into five gallons of water, and let it stand thirty minutes before using; then put in your fruit, or pour the liquid over it." It is stated that it will not change the flavor. The vessels must be sealed. It is claimed that this recipe is patented, and on the certificates of right to use, threats of prosecution for infringement are

made. We are informed that the agent selling the recipe, took away from Augusta about three hundred dollars. As to the value of this preparation for preserving meats, etc., Boracic Acid has been used for many years, and so far as known, without deleterious effects. As to Salicylic Acid, we cannot speak so positively. It has been considerably used in medicine, and sometimes with unpleasant effects. The quantity here is small compared with the medicinal dose, still we can not advise its promiscuous use. We do not know what may be the effect of continuously taking it in small quantities. The effect of the Carbonate of Soda, would be to neutralize the two acids, at least in part. The matter is an important one in a sanitary point of view, and should receive the attention of the health boards.

Amerikanischer Agriculturist.

The *Amerikanischer Agriculturist* is the only purely German Agricultural paper in the United States, and in the world for that matter. It is especially adapted for all farmers, gardeners, and housekeepers speaking the German tongue. It is all original and gives a world of matter of great value and interest. It gives the most important information to every German coming to this country, and every emigrant from the fatherland, should have it placed in his hands the moment he touches our shores.

Every one of our English subscribers who has a German in his employ, should see that he has the German *American Agriculturist*. The price is \$1.50 per year, single numbers 15c. We will send a specimen copy to any address on receipt of two 2c. stamps. Will every one of our English subscribers please see that every one of their German friends and acquaintances sends for a specimen copy of this paper. Address, *American Agriculturist*, Orange Judd Co., Publishers, 751 Broadway, N. Y.

Clubs of Subscribers to the *American Agriculturist* can at any time be increased by remitting for each addition, the price paid by the original members; or a small club may be made a larger one at reduced rates, thus: One having sent 5 subscribers and \$6, may afterwards send 5 names more and \$4, making 10 subscribers for \$10.00; and so for any of the other club rates.

Bogus vs. Genuine Insurance.

The appalling number of Insurance Companies, which have been wholly or in part wrecked by genteel scoundrels during the past few years, naturally shakes public confidence in all kinds of insurance. Many of the genteel wreckers ought now to be in State prison; indeed, we know several of them who would be there, did they not by corrupt means influence legislation, or because the statute of limitations prevents the iron hand of the law from being laid upon them. Still the fell epidemic in Insurance Companies has not been without its beneficial results. While impairing confidence in Companies generally, it has shown just what Companies could and should be trusted. Among the very first of these is the Travelers' Insurance Co., of Hartford, Conn., which is both Life and Accidental. If we remember rightly, the *American Agriculturist* has never before recommended but two Insurance Companies to the consideration of its readers. We now direct their attention to the Travelers, because we have absolute faith in its management, and because its figures and statistics for the past year show that it rests upon sure foundations.

Asbestos Roofing.—The "N. Y. Tribune"

warmly endorses the Asbestos Roofing manufactured by H. W. Johns Mfg Co., "as a light, portable, easily applied, and practically a fire-proof roofing."—What our contemporary says, we fully endorse. In fact, we have for many years recommended this roofing to our readers, because in our own experience, we have found it superior to anything else of the kind manufactured, and because we have yet to hear any complaint from the readers of the *American Agriculturist* whom we have urged to use it. To assist purchasers in selecting shades and colors, the manufacturers send free, upon application, sample sheets showing forty standard colors and tints. They likewise issue a pamphlet on "Structural Decorations," giving hints and suggestions in painting and decorating. The company also manufactures roof, car, and bridge paints, and have recently commenced to make strictly pure colors in oil. We presume our readers can procure all the information they desire from them regarding paints.

Some New Books.

Mrs. Elliott's Housewife.—Containing Practical Receipts in Cookery. By Mrs. Sarah Elliott. Revised and brought down to date by the author. Mrs. Elliott is a resident of a Southern State, and a large share of the recipes in the work are for the preparation of food in a manner popular with Southerners. This makes the present work quite unlike any other, and no matter how many works on cookery a house-keeper may have, this will be a valuable addition. Especial attention is given to preparing food for the sick, the chapter on this being very full. The talks upon domestic economy interspersed throughout, are marked by good sense and practical knowledge.

Florida and Game Water Birds of the Atlantic Coast, and the Lakes of the United States. Mr. Roosevelt has written up Florida from the sportsman's stand point, and any one who is fond of out-door life, with rod and gun, will follow him with deep interest as he unfolds the beauties of our Southern paradise of fine game. A yachting excursion to Florida during the winter season is most graphically described, such an one as will always rejoice the sportsman's heart, and heal the sickly body. The Second Part contains chapters on the proper season for game bird shooting; guns and gunnery; bay snipe and other sea shore hunting; ducks on the inland lakes, etc. The sportsman can here find almost anything from the definition of a hunting term to directions for building a "battery." Published by the Orange Judd Co., 751 Broadway, N. Y. Price \$2.00.

The Game Fish of the Northern States and British Provinces.—Robert Barnwell Roosevelt, author of several pleasing and instructive books of the river, woods, and farm, makes friends with the Game-fish of the New World, and advances our knowledge of their strange and interesting habits. Mr. Roosevelt is somewhat of an enthusiast, and is sure to mingle sufficient pleasantries with his facts to keep the reader in good humor. Next to a fishing or hunting excursion with this genial writer, is the perusal of his many exploits, told in his inimical charming way. "Game Fish" contains chapters on instructions in Fish and Fishing, the American Trout; Sea Trout; trip to the La Val; the Salmon; White Fish; Maseallonge; Pickerel; The Thousand Isles; Striped, Black, Rock, and other Bass, etc. The methods of propagating fish are treated at length; also flies and knots, and the interesting subject of insect life. Camp-life makes up not the least pleasing portion of this book. The work is illustrated with full-page cuts of various game-fish, hooks, flies, knots, etc., and a fine frontispiece engraving of the author. Orange Judd Co., 751 Broadway, New York. Price, \$2.

Household Conveniences.—Being the experience of many Practical Writers. Two Hundred and Twenty Illustrations. New York, Orange Judd Company. Price, \$1.50. "Carpets and furniture may be of the latest styles and costly, and yet the rooms fail to be home-like," says the preface; and almost every one has had illustrations of the truth of the remark. There are houses that are no more suggestive of home, than the show-room of a furniture ware-house. All that is in the house has been purchased, and one with means can furnish a dozen houses exactly like it. It is only when a hundred little things, each due to the skill or thoughtfulness of a member of the family, or of some friend, have accumulated, that the house has an individuality, and expresses the tastes and pursuits of those who live in it.

FEARLESS.
The only machine that received an award on both Horse-power and Thresher and Cleaner, at the Centennial Exhibition; was awarded the two last Gold Medals given by the New York State Agricultural Society on Horse-powers and Threshers, and is the only Thresher selected from the vast number built in the United States, for illustration and description in "Appleton's Cyclopaedia of Applied Mechanics," recently published, thus adopting it as the standard machine of this country. Catalogue sent free. Address MINARD HARDY, C. & S. Schenck Co., N. Y.

NORTHERN SUGAR CANE MANUAL.
By PROFS. WEBER and SCOVELL, of CHAMPAIGN, Ills. Sent free on application to

SEDGWICK STEEL WIRE FENCE.

Is the only general purpose Wire Fence in use, being a Strong Net-Work without Barbs. It will turn dogs, pigs, sheep and poultry, as well as the most vicious stock, without injury to either fence or stock. It is just the fence for farms, gardens, stock ranges and railroads, and very neat for lawns, parks, school lots and cemeteries. Covered with rust-proof paint (or galvanized) it will last a life-time. It is Superior to Boards or Barbed Wire in every respect. We ask for it a fair trial, knowing it will wear itself into favor. The Sedgwick Gates, made of wrought iron pipe and steel wire, defy all competition in neatness, strength and durability. We also make the best and cheapest All Iron Automatic or Self-Opening Gate, also Cheapest and Neatest all Iron Fence, Best Wire Stretcher and Post Auger, also Manufacture Russell's excellent Wind Engines for pumping water, or geared engines for grinding and other light work. For prices and particulars ask hardware dealers, or address, mentioning paper,

SEDGWICK BROS. Mfrs., Richmond, Indiana.

GET THE BEST A NEW BUTTER-WORKER TRY ONE

After three years of practical trial and public endorsement, we offer to Dairymen and to the Trade, our HAND BUTTER-WORKER, operating on the principle of direct and powerful pressure, instead of rolling, grinding, or sliding upon the butter.

We claim that it is the only Butter-Worker which will certainly, quickly and easily, take out all the buttermilk, and which does not and cannot injure the grain of the butter. It works in the salt as easily and as well.

THE GENUINE BLANCHARD CHURN GET THE BEST

Five Sizes made for Family Dairies. Eight sizes for Factory use. We now make both the Round and Square form of Factory Churns. All our goods are of perfect stock and the best workmanship. They are strong, simple, efficient, convenient and durable. The continue to be

THE FERGUSON

BUREAU CREAMERY.

It makes the most and best butter. It uses the least fuel, and saves the most labor. Hundreds have discarded deep setters and adopted the Bureau. Highly endorsed by leading Dairymen.

DON'T BUY ANY CANS, PANS OR CREAMER, or send your milk to the factory, until you have sent for our large illustrated circulars and price lists.

THE FERGUSON MFG. CO., Burlington, Vt.

Stockbridge Manures.

Prices Reduced. Standard Maintained.

The Massachusetts Fertilizer Inspector's Valuations of the STOCKBRIDGE MANURES } Average \$44.48 per Ton
for the past seven years

The Average Price for 1884 will be \$4.50 per bag, or \$5 a ton less than last year.

In buying a fertilizer, its quality and by whom manufactured should be considered along with the price per ton. A ton of good English hay is considered by most farmers cheaper at \$20 than a ton of bog-meadow hay at \$10; and for the same reason the Stockbridge Manures, which are made largely from chemicals, and are very concentrated, are cheaper at the prices asked than many fertilizers at half the price. They have stood the test of the field and State Inspectors for nearly ten years, and have been found the most reliable and richest fertilizers offered in the market. The fact that they have been well made in the past should be a sufficient guaranty of their strength and purity in the future; but, notwithstanding this, we are still under bonds to Prof. STOCKBRIDGE to maintain their standard. Send for pamphlet (mailed free), to

BOWKER FERTILIZER CO.,
43 Chatham St., Boston, Mass.

Good Books for May.

EITHER OF THESE BOOKS SENT POST-PAID ON RECEIPT OF PRICE.

FARM and GARDEN.

Broom Corn and Brooms.

A Treatise on Raising Broom-Corn and Making Brooms on a Small or Large Scale. Illustrated. Paper, .50; Cloth, .75

Chemistry of the Farm.

Treating with the utmost clearness and conciseness, and in the most popular manner possible, of the relations of Chemistry to Agriculture, and providing a welcome manual for those, who, while not having time to systematically study Chemistry, will gladly have such an idea as this gives them of its relation to operations on the farm. By R. WARINGTON, F. C. S. Cloth, 12mo. 1.00

Colorado as an Agricultural State.

Its Farms, Fields, and Agricultural Lands. Of great interest to all who would know the agricultural resources of this State, the growth of which has been hitherto unparalleled. By WILLIAM E. PABOR, Associate Editor of the "Colorado Farmer." Illustrated. Cloth. 1.50

Elements of Agriculture.

This is one of the works which no Farmer's son, whether his books be few or many, should fail to own and read. It will make him a better and more successful farmer. By GEO. E. WARING, JR. Cloth. 1.00

Gardening for Young and Old.

A work intended to interest Farmers' Boys in Farm-Gardening, which means a better and more profitable form of Agriculture. The teachings are given in the familiar manner so well known in the author's "Walks and Talks on the Farm." By JOSEPH HARRIS. Illustrated. Cloth, 12mo. 1.25

Harris Insects Injurious to Vegetation.

Enlarged and Improved. With additions from the author's manuscripts and original notes. By the late THADDEUS WILLIAM HARRIS, M.D. Illustrated by Engravings drawn from Nature, under the supervision of Professor AGASSIZ. Edited by Hon. CHARLES L. FLINT. This work is fully illustrated with two hundred and seventy-eight fine wood-cuts, and eight beautiful steel plates, full-page size, containing ninety-five figures. Published in two beautiful editions; one plain, with steel engravings, extra cloth; the other in extra cloth, beveled boards, red edges, engravings colored with great accuracy. Octavo, 640 pages. Cloth, 8vo. Plain, 4.00; Colored Plates, 6.50

Harris' Talks on Manures.

Revised and Enlarged by the Author. A series of familiar and practical Talks between the Author and the Deacon, the Doctor, and other Neighbors, on the whole subject of Manures and Fertilizers. Including a chapter specially written for it by Sir John Bennet Lawes, of Rothamsted, England. By JOSEPH HARRIS, M. S., author of "Walks and Talks on the Farm," "Harris on the Pig," etc. Cloth, 12mo. 1.75

Henderson's Gardening for Profit.

A now well known and standard work on Market and Family Gardening. The author's own successful experience of nearly 30 years, enables him to give most valuable information. By PETER HENDERSON. Finely Illustrated. Cloth, 12mo. 1.50

Henderson's Gardening for Pleasure.

This work is prepared to meet the wants of all classes in Country, City, and Village, who keep a garden for their own enjoyment rather than for the sale of products. It is adapted to the wants of the amateur in indoor and out-door gardening. It is one of the best guides to Window Gardening we know of. By PETER HENDERSON. Illustrated. Cloth, 12mo. 1.50

Henderson's Practical Floriculture.

A Guide to the Successful Propagation and Cultivation of Florists' Plants. In this work, which has everywhere become so deservedly popular, not only is the whole "art and mystery" of propagation explained, but the reader is taught how to plant and grow the plants after they have been propagated. By PETER HENDERSON. Beautifully Illustrated. Cloth, 12mo. 1.50

New American Farm Book.

Originally by R. L. ALLEN. New, revised, and enlarged edition, by L. F. ALLEN. There is no other work, of equal value to this, upon the subjects of which it treats. The old work stood in the front rank, and the revised and enlarged edition more than maintains its advanced place. Cloth. 2.50

Quinn's Money in the Garden.

The author gives, in a plain, practical style, instructions on three distinct, although closely connected, branches of gardening—the kitchen garden, market garden, and field culture, from successful practical experience for a term of years. Illustrated. Cloth, 12mo. 1.50

Riley's Potato Pests.

An Illustrated Account of the Colorado Potato-beetle and the other Insect Foes of the Potato in North America. With Suggestions for their Repression and Methods for their Destruction. By CHARLES V. RILEY, M. A., Ph. D. Illustrated. 12mo. Paper, .50; Cloth, .75

Roe's Play and Profit in my Garden.

The reader is told how, after four years' experience, the author managed to secure a profit of \$1000, while at the same time carrying on pastoral and literary work. By Rev. E. P. ROE. Cloth, 12mo. 1.50

Silos and Ensilage.

The Preservation of Fodder Corn, and other Green Fodder Crops. Bringing together the most recent information, from various sources. Edited by Dr. GEORGE THURBER. Fully Illustrated. Cloth, 12mo. .50

Sweet Potato Culture.

The Sweet Potato is no longer a rare thing in any but the northern-most localities, being successfully cultivated in many places further north than Virginia. This little book supplies the want, not before met, of a guide to its culture. By JAS. FITZ, Author of "Southern Apple and Peach Culturist." Paper cover. .40

Treat's Injurious Insects of the Farm and Garden.

One of the most important needs of the tiller of the soil is a knowledge of insect pests to vegetation. In this work, which is made more valuable by its abundant illustrations, Mrs. Treat gives the results of her own observations, and also most valuable selections from other sources. By MARY TREAT. Cloth. 2.00

Truck Farming at the South.

A work giving the experience of a successful grower of vegetables or "garden truck" for Northern markets. Essential to any one who contemplates entering this promising field of Agriculture. By A. OENLER, of Georgia. Illustrated. Cloth, 12mo. 1.50

White's Gardening for the South.

An admirable work on Gardening, which will be found especially valuable to those living in the Southern States, as it gives the varieties of vegetables and fruits adapted to the South, and the necessary modes of culture. By the late WILLIAM N. WHITE, of Athens, Ga., with additions by Mr. J. VAN BUREN and Dr. JAMES CAMAK. Illustrated. Cloth, 12mo. Price, post-paid, 2.00

FRUITS and FLOWERS.

Barry's Fruit Garden.

This book, in its earliest editions, has always been regarded as standard authority. The author has had more than thirty years' practical experience at the head of one of the largest nurseries in this country. New Edition, thoroughly revised by the author. By P. BARRY. Cloth. 2.50

Chorlton's Grape Grower's Guide.

Intended especially for the American climate; being a practical Treatise, with Engravings, on the Cultivation of the Grape-vine in each Department of Hot-House, Cold Grapery, etc.; with Plans for the Construction and Heating. By WM. CHORLTON. Illustrated. Cloth, 12mo. .75

Elliott's Hand-Book for Fruit Growers.

For those who grow fruit for their own use, with an Addenda, treating on flowering shrubs, roses, etc. By F. R. ELLIOTT. With 60 Illustrations. Paper, .60; Cloth, 1.00

Fuller's Grape Culturist.

This is one of the very best of works on the Culture of the Hardy Grapes, with full directions for all departments of Propagation, Culture, etc., with 105 excellent Engravings, illustrating Planting, Training, Grafting, etc. By ANDREW S. FULLER, Practical Horticulturist. Cloth, 12mo. 1.50

Fuller's Small Fruit Culturist.

Rewritten, enlarged, and brought fully up to the present time. This is the first work exclusively devoted to Small Fruits, and it continues to be the recognized authority. It is equally adapted to the needs and requirements of the private cultivator and the market grower. This book covers the whole ground of Propagating Small Fruits, their Culture, Varieties, Packing for Market, etc. By ANDREW S. FULLER. 1.50

Fuller's Strawberry Culturist.

A practical little work, meeting with universal favor. It gives a full list of varieties. Paper cover, 12mo. .20

Fulton's Peach Culture.

This is the only practical Guide to Peach Culture on the Delaware Peninsula, and is the best work upon the subject of Peach Growing for those who would be successful in that culture in any part of the country. It has been thoroughly revised, and a large portion of it rewritten by Hon. J. ALEXANDER FULTON, the author, bringing it down to date. Cloth, 12mo. 1.50

Husmann's American Grape-Growing and Wine-Making.

New, revised, and enlarged edition. By Professor GEORGE HUSMANN. With Contributions from well-known Grape-Growers, giving a wide range of experience. The best work on the subject. Cloth, 12mo. 1.50

Mohr on the Grape Vine.

This is a very plain discussion of the structure of the Vine, and the principles involved in its pruning, training, and cultivation generally. By Prof. FREDERICK MOHR. Illustrated. Cloth, 12mo, 1.00

My Vineyard at Lakeview.

This book tells just what the beginner in grape culture wishes to know, with the charm that always attends the relation of personal experience. Illustrated. Cloth, 12mo. 1.25

Parsons on the Rose.

A Treatise on the Propagation, Culture, and History of the Rose. By SAMUEL B. PARSONS. New, Revised and Enlarged Edition. Brought down to date. Elegantly Printed, and Beautifully Illustrated. Cloth, 12mo. Price, post-paid, 1.50

Quinn's Pear Culture for Profit.

Teaching how to raise Pears intelligently, and with the best results, how to find out the character of the soil, the best mode of preparing it, the best varieties to select under existing conditions, the best mode of planting, pruning, fertilizing, grafting, etc. Illustrated. By P. T. QUINN, Practical Horticulturist. Cloth, 12mo. 1.00

White's Cranberry Culture.

Contents:—Natural History.—History of Cultivation.—Choice of Locations.—Preparing the Ground.—Planting the Vines.—Management of Meadows.—Flooding.—Enemies and Difficulties Overcome.—Picking.—Keeping.—Profit and Loss.—Letters from Practical Growers.—Insects Injurious to the Cranberry. This is one of the very best and most practical works upon Cranberry Culture that have ever been issued. By JOSEPH J. WHITE, A Practical Grower. Illustrated, Cloth, 12mo. 1.25

PATENTS. Lenox Simpson & Co., Washington, D. C., Lawyers, formerly Examiners in the Patent Office. Attorneys in more than 16,000 cases. Familiar with every branch of the business. Describe case and write for terms.

MUNN & CO'S PATENTS
ESTABLISHED 1846
New York
We continue to act as solicitors for patents, caveats, trade-marks, copyrights, etc., for the United States, and to obtain patents in Canada, England, France, Germany, and all other countries. Thirty-six years' practice. No charge for examination of models or drawings. Advice by mail free. Patents obtained through us are noticed in the SCIENTIFIC AMERICAN, which has the largest circulation, and is the most influential newspaper of its kind published in the world. The advantages of such a notice every patentee understands. This large and splendidly illustrated newspaper is published WEEKLY at \$3.20 a year, and is admitted to be the best paper devoted to science, mechanics, inventions, engineering works, and other departments of industrial progress, published in any country. Single copies by mail, 10 cents. Sold by all news-dealers. Address, Munn & Co., publishers of Scientific American, 261 Broadway, New York. Handbook about patents mailed free.

Last Call!

HUNDREDS OF PREMIUMS

Offered to Our Subscribers.

We again call the attention of all our Readers to the

ILLUSTRATED PREMIUM LIST.

Containing Thirty-six pages, with a large number of Engravings, describing elegant Premiums, offered to our subscribers.—This List was made up in October last and the offer holds good

To the End of June.

Every one who has not received a copy, or who has lost or mislaid the copy received, is invited to send his address for one, by Postal Card or otherwise.—Also the address of any friend who will be interested in receiving a copy. A copy will be mailed post-paid to all desiring one.

New Book Premiums.

See the offer on page 185 of the April *American Agriculturist*.

Our New Microscope.

We would call attention to the new Microscope, a full description of which was given in the March number (pages 142 and 143), and one of which we will present, delivered free, with the *American Agriculturist*, post-paid, to any new subscriber for 1884 for two dollars. Any person who is already a subscriber to the *American Agriculturist*, can have one of these Microscopes delivered free for one dollar and twenty-five cents.

Do you want to get a Worcester's Unabridged Dictionary free? — Write us, and we will tell you how you can do it?

Extended to June First.

The magnificent offer of Premium books, as fully described on page 140 of the March 1884 *American Agriculturist*, is extended to June 1st.

To any one sending us, before June 1st, one new subscription at our regular rate of \$1.50 a year, and 10c. extra for postage, we will forward any one of the four premium books. "Farm Conveniences," "Household Conveniences," "Cottage Houses," and "Barn Plans and Out-buildings." This offer does not include any other premium.

Valuable Watches as Premiums

Send to us for circular descriptive of twelve different Watches, any of which will be sent as Premiums for subscribers to the *American Agriculturist* sent before June 1. Address the Publishers.

Catalogues Acknowledged.

SEEDSMEN.

R. H. ALLEN & Co., Nos. 189, 191 Water St., New York City.—Besides vegetable and flower seeds, unusually full in grasses, grains, and other farm seeds. Also garden implements and requisites.

B. K. BLISS & SONS, No. 34 Barclay St., New York City.—As full as usual with many novelties in vegetables and flowers. Also plants, small fruits, garden tools, etc., etc.

G. R. CLARK & Co., Scranton Pa.—Seeds, vegetable plants, greenhouse, and other plants etc.

E. L. MEYERS, Hutchinson, Kansas.—Besides the newer vegetable and flower seeds, agricultural and tree seeds, and useful essays on silk, tree, and grass culture, etc.

PAGE & KELSEY, Des Moines, Iowa.—Besides seeds of all kinds, greenhouse, and other plants, and implements in great variety are offered.

J. H. & W. E. CONE, Hartford, Conn.—Offer the celebrated Wethersfield garden seeds, and deal largely in grass seeds.

PARKER, GANNETT & WOOD, 49 N. Market St., Boston, Mass.—Besides seeds, and a long list of specialties, choice plants, ornamental trees, small fruits, fertilizers, and implements.

A. D. PERRY & Co., Syracuse, N. Y.—Compact seed lists, and very full in implements, some of which are quite new.

PRINGLE & HORSFORD, Charlotte, Vt.—A number of specialties in wheat, oats, and other grains, also vegetable seeds of choice varieties that originated with them.

PARHAM, RANDLE & Co., Litchfield, Ill.—Seed potatoes and vegetable plants in variety.

E. A. REEVES & Co., No. 68 Cortlandt St., New York City.—A very full descriptive list, with novelties.

J. B. ROOT & Co., Rockford, Ill.—A carefully selected list, with useful notes.

W. E. WELD, Ingleside, Steuben Co., N. Y.—Special list of seed potatoes.

NURSERYMEN.

G. G. BENEDICT, Delaware, Ohio.—Strawberry and Raspberry Plants and Seed Potatoes.

CHAS. J. BLACK & Bro., Hightstown, N. J.—General nursery stock, very full in peaches, also greenhouse plants.

JOHN G. BURROW, Fishkill, N. Y.—Grape vines and small fruits generally.

A. J. CAYWOOD, Marlboro, N. Y.—Special circular, descriptive of the Duchess Grape and the Marlboro Raspberry.

O. S. CHAPIN, San Diego, Cal.—General fruits and ornamental stock, with varieties suited to the country.

MATTHEW CRAWFORD, Cuyahoga Falls, Ohio.—Though called a "strawberry catalogue," it has other small fruits, and is a compact treatise on strawberry culture.

ELLWANGER & BARRY, Rochester, N. Y.—Issue a supplemental catalogue offering new and scarce varieties in the different departments of their immense nurseries.

A. D. FIELD, In laola, Iowa.—Fruit and other trees at very low prices.

CHAS. F. GARDNER, Osage, Iowa.—General stock, and strong in forest trees.

J. R. KINNAN, Rising City, Neb.—Small fruits and forest tree seedlings.

JACOB W. MANNING, Reading, Mass.—A special spring list of a very large stock.

GEORGE L. MILLER, Stockton P. O., Butler Co., Ohio.—Small fruits and greenhouse plants.

WM. H. MOON, Morrisville, Pa.—An interesting catalogue, and up to the times.

PARSONS & SONS COMPANY, Flushing, N. Y.—A collection of ornamental trees and shrubs, unequalled in this country, and by few abroad.

STORRS, HARRISON & Co., Painesville, Ohio.—This extensive nursery, besides fruits and flowers in this catalogue, add vegetable and flower seeds.

FLORISTS.

P. J. BERCKMANS, Augusta, Ga.—A full collection, especially of plants suited to the South.

ELLWANGER & BARRY, Rochester, N. Y.—Have of late years devoted much attention to rose culture. Their special Rose Catalogue for this spring, is not only extremely full, but is a wonder of careful arrangement.

FRED. W. KELSEY, No. 208 Broadway, New York City.—Represents the Compagnie Continentale d'Horticulture (formerly J. Linden), the great establishment for new and rare plants at Ghent, Belgium.

JOHN SAUL, Washington, D. C.—As usual, novelties in choice plants are numerous. A special Rose List and a plate of fine Moss Roses.

EDWARD D. STURTEVANT, Bordentown, N. J.—Rare water lilies and other aquatics, and general greenhouse stock.

J. M. THORBURN & Co., No. 15 John St., New York City.—Special gladioli list, other spring bulbs and small fruits.

PHIL. STUBLER, Naperville, Ill.—Small fruits with directions for culture.

J. A. DEVEER, No. 318 Broadway, New York City.—Represents Ant. Roozen & Son, celebrated bulb growers at Overveen, near Haarlem, Holland.

WILLIAM C. WILSON, 45 West 14th St., New York City.—A large catalogue, including all departments of horticulture, each well filled with the newest and best.

MISCELLANEOUS.

Under this head are classed all the catalogues that could not be properly arranged in the other divisions.

ASHLEY PHOSPHATE COMPANY, Washington, D. C.—Two pamphlets are sent. One is an almanac, with ludicrous engravings and matter intended to call popular attention to their fertilizers. The other is mainly a description of "Floats," a very fine powder, which is the form in which the phosphate rock is now largely applied.

W. J. BAKER & Bro., No. 215 Pearl St., New York City. In a pamphlet entitled: "Facts for Farmers," is given an account of the numerous fertilizers made by this firm, and testimonials from those who have used them.

JACOB H. BEAN, Decatur, Ill.—Illustrates and describes his Hay Stacker, Hay-Loader, Hay-Roof, and other apparatus for facilitating the curing of the hay crop.

T. B. EVERETT & Co., 43 South Market St., Boston, Mass.—A large, finely illustrated catalogue of farm implements, including the most recent; also dairy apparatus.

W. H. FAY & Co., Camden, N. J.—Fay's Waterproof Manila, with illustrations showing the manner of applying it to temporary buildings, etc.

FREEPORT MACHINE CO., Freeport, Ill.—The makers of the Stover Wind-mill announce their removal to enlarged quarters.

H. B. GRIFFING & Co., No. 70 Cortlandt St., New York City.—Farm Implements in large variety, also fertilizers of all kinds.

PETER HENDERSON & Co., No. 35-37 Cortlandt St., New York City.—Appear as implement dealers and issue an immense fully illustrated catalogue of their stock in this line.

JOHN B. HOWE, Seneca, Ill.—Poland-China Swine and High-Class Poultry. A treatise on both as well as a catalogue.

H. H. HUTCHINS, Fennville, Mich.—A New Wire Stretcher.

ALFRED LEIDA, Delaware Station, N. J.—Makes a specialty of Plymouth Rock fowls.

WM. E. LINCOLN & Co., Warren, Mass., and London; Ont.—A full description of the "Channel Can Creamery."

C. M. LUFKIN, Oltstead, N. H.—Illustrates and describes the Lufkin Swivel Plow.

THE MAPES FORMULA AND PERUVIAN GUANO CO., 158 Front St., New York.—Prepare special fertilizers for tropical fruits, and issue a catalogue describing them.

CHARLES MILLAR & SON, Utica, N. Y.—Cheese Factory and Dairy Apparatus in great variety and illustrated.

R. B. MITCHELL, Arlington Heights, Cook Co., Ill.—Issues the "Summer Lawn Poultry Book," which is both a treatise on poultry keeping, and an illustrated catalogue of an extensive poultry establishment.

NEW YORK PLOW CO., 55 Beekman St., New York City.—A handsome illustrated list of the great variety of machines and implements made by them.

L. H. OLMSTED, Corona, N. J.—Describes the mole and its ways, and his trap for catching the troublesome creature.

THURSTON & BRIGHAM, Buffalo, N. Y.—A special catalogue of cutlery.

NATIONAL IRON FENCE CO., No. 22 Cortlandt St., New York City.—Illustrate their fence with the Carpenter Iron Post.

THE UNIVERSAL JOINT CO., No. 30 Broad St., New York City.—Illustrate the working of the Lightning Horse-Cleaning Machine.

P. B. SHELTON, Erie, Pa.—Describes Waldo's Combined Road-Builder and Grader, which proposes to do the operations of road-making and repairing, much quicker and cheaper than in the ordinary manner.

WALES MANUFACTURING CO., Syracuse, N. Y.—The Barry Lawn Rake Attachment, a simple device for clearing the rake of litter, leaves, grass, etc.

ZIMMERMAN MANUFACTURING COMPANY, Cincinnati, O., and Burlington, Iowa.—A full description of the Zimmerman Fruit Dryer or Evaporator.

FOREIGN CATALOGUES.

VILMORIN, ANDRIEUX & Co., Paris, France.—A wonderfully full list of seeds of all kinds and, as usual, finely illustrated.

HEINRICH WREDE, Lüneburg, Germany.—A special list of Pansy seeds, forty-seven distinct varieties.

V. INGENOLI, Milan, Italy.—Wholesale list of specialties in Farm and Garden Seeds.

WILLIAM BROTHERS, Henaragoda, Ceylon.—An interesting catalogue, offering Cinchona, Coffee and Cardamom Seeds, with nutmeg and other tropical plants, etc.

The Weed Lists.

I am only able to announce the names of the prize-winners. The particulars will be given next month. Maggie E. Benton, Livingston, Mo.; Mamie Pepon, Warren, Joe Davies Co., Ill.; Jas. F. A Treatise on the Bovine Species in General. An entirely new translation of the last edition of this popular and instructive book. By THOS. J. HAND, Sec'y of the American Jersey Cattle Club. With over 100 illustrations, especially engraved for this work. Cloth, 12mo. 1.00

Keeping One Cow.

A collection of Prize Essays, and selections from a number of other Essays, with editorial notes, suggestions, etc. This book gives the latest information, and in a clear and condensed form, upon the management of a single Milch Cow. Illustrated with full-page engravings of the most famous dairy Cows. Cloth, 12mo. 1.00

Youatt and Martin on Cattle.

Being a Treatise on their Breeds, Management, Diseases; a full history of the various races; their origin,

breeding, and merits; their capacity for Beef and Milk. By W. YOUATT and W. C. L. MARTIN. Edited by AMBROSE STEVENS. Cloth, 12mo. 1.50

Stewart's Shepherd's Manual.

Plain enough for any farmer to learn how to manage a flock successfully, though he may never before have kept a sheep, and comprehensive enough for an experienced shepherd to gather valuable suggestions from it. By HENRY STEWART. Illustrated. Cloth, 12mo. Post-paid. 1.50

Coburn's Swine Husbandry.

New, revised, and enlarged edition of this most valuable work on the Management of Swine and Prevention and Treatment of their Diseases. By Hon. F. D. COBURN. Cloth. 1.75

Harris on the Pig.

New Edition. Revised and Enlarged by the Author. The various English and American Breeds are discussed. A work of equal value to the farmer who keeps but few pigs, and to the large breeder. 1.50

POULTRY, Etc.

Stoddard's An Egg Farm.

The management of Poultry in large numbers, being a series of articles written for the *American Agriculturist*. With other articles. Contents: Introduction. —Plan of Farm.—Manner of Feeding.—Location of Farm.—Kind of Soil.—Crops on the Farm.—Supplying Water and Food.—Collecting and Storing Dry Earth.—Houses for Layers.—Feeding House for Winter.—Houses for Sitters.—Arrangements for Breeding Stock. Paper Cover, .50; Cloth, .75

The American Standard of Excellence in Poultry.

As revised by the American Poultry Association at their Convention, held at Chicago, January 24th, 1876. Flex. cloth, 12mo. 1.00

Tegetmeier's Poultry Book.

New edition, greatly enlarged. Comprising the Breeding and Management of Profitable and Ornamental Poultry; to which is added the Standard of Excellence in Exhibition Birds. The book is beautifully illustrated with 32 full plate Colored Engravings, besides numerous plain Engravings by Harrison Weir. By W. B. TEGETMEIER. Cloth, 8vo., full gilt, and gilt edges. 9.00

Wright's Practical Poultry Keeper.

A complete and standard Guide to the Management of Poultry, for domestic use, the markets, or exhibition. This book is a valuable manual for everybody who feeds chickens or sells eggs. It suits at once the plain poultryer who must make the business pay, and the chicken fancier whose taste is for gay plumage, and strange, bright birds. These chapters were written with the intention of producing a manual so plain, minute, and practical, that any one could, by using it as a guide, with no previous experience with poultry, become at once successful in producing eggs, young chickens, and fat fowls for market. Illustrated. By L. WRIGHT. Cloth, 12mo. 2.00

Canary Birds.

A complete Guide for their Breeding, Rearing, and Treatment, together with hints and suggestions regarding Cages, Aviaries, etc. New edition. 24mo. Paper, .50; Cloth, .75

The American Bird Fancier.

New edition. How to Breed, Rear, and Care for Song and Domestic Birds. .50

Quinby's New Bee-Keeping.

The Mysteries of Bee-keeping Explained. Combining the results of Fifty Years' Experience, with the latest discoveries and inventions, and presenting the most approved methods, forming A Complete Guide to Successful Bee-Culture. By L. C. ROOR. With 100 Illustrations, and a portrait of M. Quinby. Cloth, 12mo. \$1.50

MISCELLANEOUS.

Farm Conveniences.

A Manual of what to do, and how to do it. Describing all manner of Home-made Aids to Farm Work. Made up of the best ideas from the experience of many practical men. With over two hundred Engravings, 1.50

Household Conveniences.

With over two hundred Engravings. A most useful volume, filled with valuable Hints and Suggestions for doing all kinds of work in the Household. 1.50

Leland's Farm Homes, In-Doors and Out-Doors.

A most interesting book, full of good suggestions, by one who fully understands the subject. By E. H. LELAND. Illustrated. Cloth, 12mo. Price, post-paid. 1.50

Barn Plans and Out-Buildings.

Two Hundred and Fifty-seven Illustrations. A Most Valuable Work, full of Ideas, Hints, Suggestions, Plans, etc., for the Construction of Barns and Out-buildings by Practical Writers. Chapters are devoted, among other subjects, to the Economic Erection and Use of Barns, Grain Barns, House Barns, Cattle Barns, Sheep Barns, Corn Houses, Smoke Houses, Ice Houses, Pig Pens, Granaries, etc. There are likewise chapters upon Bird Houses, Dog Houses, Tool Sheds, Ventilators, Roofs and Roofing, Doors and Fastenings, Work Shops, Poultry Houses, Manure Sheds, Barn Yards, Root Pits, etc. Recently published. Cloth, 12mo. 1.50

Cottage Houses for Village and Country Homes.

Together with Complete Plans and Specifications. General descriptions, and detailed estimates of materials, construction, and cost, are given with each plan—by which any intelligent person may readily comprehend the character of the buildings, and which will enable any builder of ordinary experience to prepare his estimates—corrected by the varying circumstances of locality and prices, and proceed to their erection. Nearly all these plans have been built from, and their practicability proven. They embrace a great variety of arrangement, and are adapted to meet the general want for convenient, comfortable, and economic Homes. By S. B. REED, ARCHITECT, Author of "House Plans for Everybody," etc. With over one hundred Illustrations. Cloth, 12mo. 1.25

Reed's House Plans for Everybody.

This useful volume meets the wants of persons of moderate means, and is already among the Standard Architectural Books. It gives a wide range of design, from a dwelling costing \$250 up to \$8,000, and adapted to farm, village, and town residences. Nearly all of these plans have been tested by practical workings. They provide for heating, ventilation, etc., and give a large share of what are called Modern Improvements. One feature of the work imparts a value over any similar publication of the kind that we have seen. It gives an Estimate of the Quantity of every article used in the construction, and the cost of each material at the time the building was erected, or the design made. Even if prices vary from time to time, one can, from these data, ascertain within a few dollars the probable cost of constructing any one of the buildings here presented. By S. B. REED. Profusely Illustrated. Bound in Cloth, black and gold. 12mo. 1.50

A Profitable Investment!

Each \$5 doubled monthly, and loss rendered impossible.

"HOME, SWEET HOME."

\$10 Monthly Buys Your Own.

At HINSDALE CITY, 13 miles from New York, 35 minutes by rail, and 5 minutes extra Brooklyn Bridge or Ferry. Several thousand building lots surrounding Hinsdale depot, price \$165 each, selling on monthly payments of \$5 per lot; Cottages \$10 monthly upwards. Lots advanced \$5 each monthly, until present prices are at least doubled. New York will be the future CITY OF THE WORLD, property in and around it is, and will continue to increase in value. Hinsdale adjoins Garden City—the most beautiful of all cities—and Creedmoor Rifle Range, and is the Long Island U. P. Junction for both. Commutation averages 40c. per trip. Lots are doubling in value while being paid for. For investment, residence, or summer resort, it is equally desirable. Climate, drives and surroundings unsurpassed. Building optional. Success assured. Extensive improvements contemplated. Agents wanted. Circulars, &c., of

Smooth Bore Muskets altered to Breech

Loaders, using brass or paper shells No. 12, 36-inch barrel, rel. 8½ to 9 lbs. Warranted good shooter 60 to 75 yards. Choke-bored, only \$4.50—or express paid, \$5.50—re-loadable paper shells, with metal base, \$1.00 per 100; Brass shells, 75c. per dozen; Loading outfits complete, \$3.00 a set; Fine leather hunting and shot bag, \$1.25; Vads, 20c. a box, primers for reloading shells, 40c. a box of 250. Address, J. H. JOHNSTON, Great Western Gun Works, 621 Smithfield Street, Pittsburgh, Pa.

(Continued from last month.)

How Watch Cases are Made.

A plate of SOLID GOLD 14 2-10 karats fine is soldered on each side of a plate of hard nickel composition metal, and the three are then passed between polished steel rollers. From this plate the various parts of the cases—backs, centers, bezels, etc. are cut and shaped by dies and formers. The gold is thick enough to admit of all kinds of chasing, engraving, and engine-turning. The composition metal gives it needed strength, stiffness and solidity, while the written guarantee of the manufacturers warranting each case to wear twenty years proves that it contains all the gold that can possibly be needed. This guarantee is given from actual results, as many of these cases have been worn perfectly smooth by years of use without wearing through the gold.

DUBUQUE, IA., Dec. 14, 1880.

I have used one of your James Boss' Gold Watch Cases for seventeen years. I bought it second-hand and know of its having been used before I got it, but do not know how long. It looks good for ten years longer. Did not suspect it was a filled case until so informed by a jeweler a short time since. I most cheerfully recommend your cases to be all they are represented to be, and more.

O. McCRAVEY, Dep. Col. Int. Rev. 3d Dis. Iowa.

Send 3 cent stamp to Keystone Watch Case Factories, Philadelphia, Pa., for handsome illustrated Pamphlet showing how James Boss' and Keystone Watch Cases are made.

(To be Continued.)

ALLEN'S ROOT BEER EXTRACT

which will make 6 gallons of Beer. No trouble to make. No boiling. No straining. Much preferable to ice water. Made entirely of roots and herbs, such as Dandelion, Hops, Ginger, Spikenard, &c. Package of herbs for making sent by mail for 25c. CHAS. E. CARTER, Lowell, Mass.

Carriages, Wagons and Machinery Run

Without grease or oil. No occasion to take off the carriage wheels. Carriages running successfully in New York, City, Philadelphia, Pa., Jersey City, Paterson, Orange and other places. Circulars sent free. Address, GRAPHITE LUBRICATING CO., Jersey City, N.J.

SOLUBLE PACIFIC GUANO.

YEARLY SALES
50,000 Tons.

We again offer this old established and reliable Fertilizer, which during the past year has fully sustained its high reputation. For Farm Crops of all kinds, Fruit Trees, Gardens, Lawns, and Flowers, it has no superior. For sale by our agents throughout the United States. Pamphlets containing testimonials and directions forwarded free.

June Greeting.

With this number, the *American Agriculturist* completes the first half of its forty-third year. Over 3,000 congratulatory letters from subscribers within a few weeks afford most gratifying assurances that the steady improvements in this Journal are everywhere recognized. The present owners and publishers who, six years ago, assumed control and management, have freed the *American Agriculturist* from all ENCUMBRANCES, and, equipped with brains and means as never before, unhesitatingly promise a paper better and stronger with each succeeding issue. Dr. Geo. Thurber, for nearly a quarter of a century the Editor, and all the able Associates and Writers who have rendered material assistance in making the *American Agriculturist* what it is to-day — are still with us. At no period of its existence has this Company been in so prosperous and stable a condition, as it now is.

See Page 269 For Important Announcement.

Prizes for Short Stories.

The Publishers of the *American Agriculturist* offer the following prizes for short, instructive, and entertaining original stories suited to the BOYS AND GIRLS' COLUMNS.

FIRST PRIZE.....	\$50.00
SECOND PRIZE.....	\$30.00
THIRD PRIZE.....	\$15.00

The stories are to be plainly written in black ink on one side of white paper, and should not exceed three thousand words. Sketches may accompany the story whenever they will add clearness and interest to the text. The stories are to be sent to the Editors of the *American Agriculturist* on or before September 1, 1884. The real name accompanying the story should be placed in a sealed envelope, bearing the assumed name of the writer upon its face. All stories submitted for the above prizes become the property of the *American Agriculturist*. A committee of three competent persons will act as judges and make the awards.

This offer is open to both young and old, and any person may compete for all the prizes. There is no limit to the range of subjects, and the stories may be either real or imaginary, or a combination of the two.

The best time to kill weeds is when they are very small. Most of this work should be done by horse labor. Keep the cultivator running through the corn field, using the hand hoe only close to the hills. Much of the cost of tillage should be charged to the succeeding crops, otherwise figures will often show that it does not pay to grow corn, or any hoed crop. Sow a quantity of fodder corn to supply an abundance of wholesome food when the pastures get short. Sow in drills three feet apart, and at weekly intervals, that there may be a long and continuous supply. A field from which winter rye has been removed, may be manured, plowed, and sown to fodder corn.

Sow Swedish turnips now in drills two and a half feet apart. Use at least two pounds of seed per acre. It is essential to have the soil rich and mellow. When the second leaf appears, thin the plants to about fifteen inches in the rows.

Haying begins this month, and every implement should be in readiness for this pushing work. Cut only as much grass as can be well eared for, otherwise the quality of the hay will be injured by exposure. The hay tedder, next to the mowing machine, is the most valuable haying implement. It hastens the curing, and makes the hay of uniformly good quality. Hay caps made of stout cotton are excellent to protect hay while in the cock. They often pay for themselves in a single season, and if properly cared for, will last for several years.

Buckwheat may be sown in June, and is a good crop for new land. It may profitably fill up a place where some other grain crop has failed.

Live Stock Notes.

Sheep shearing needs to be done with kindness and care. We have seen the skin badly cut, and the shorn animal ill-treated in other ways. Hold the sheep firmly, yet comfortably. The sale of the wool depends somewhat upon the manner in which it is rolled and tied. Each fleece should make a package that can be handled without falling to pieces. Wool tables, or boxes for securely doing up fleeces, have been figured and described in the *American Agriculturist* from time to time. Immediately after shearing the ticks leave the shorn sheep, and gather in the longer wool of the lambs. The young stock thus infested, should be dipped in a decoction of tobacco water, or in one of the mixtures made for the purpose, and sold in the markets. June butter is considered the best made during the year, and therefore the cows now should be yielding an abundant flow of rich milk. Among the essentials of good butter making, are a plenty of wholesome food and pure water, with

clean management of the milk and cream in every way, from the milking, until the butter is packed for market. Calves that are to become milch cows, need a quiet place by themselves, and regular rations of milk and meal. They should be gently handled, and taught to lead without halter. Pigs for the early market need a good run in a pasture—clover is best, and a daily supply of bran and meal slops. The proper place for pigs is in the orchard, where they may feed upon the wormy fruit that falls, and thus destroy vast numbers of injurious insects. Rats, owls, skunks, and hawks, are natural enemies to the young chickens, and to keep them away the yards must be watched by day, and closed coops provided for the night time. The garden may be rid of many insect pests by allowing the young chicks to run among the growing crops.

Orchard and Fruit Garden.

Indications point to an abundant fruit year, though the peach crop may be injured by late frosts, or a long cold rain while the trees are in blossom, may diminish the "set" of apples and pears. These disasters are likely to be local. In years of abundance, while common and poor fruit hardly pays its carriage to market, really fine fruit brings about the usual price. It is in such years that the grower, by care in producing fine specimens, and packing them in an attractive manner, finds fruit-growing profitable, while his indifferent neighbor declares that "fruit don't pay." To produce fine specimens, the number borne by the tree must be reduced; this might have been done in the winter by pruning, but now the orchardist must rely upon thinning the fruit. If we give a single specimen the nourishment that would have been divided between three and four, the result will be seen in the extra size and beauty of the one thus favored. In no fruit is there such a difference in price between the common and extra, as in the peach, and it is a well established fact, that with peaches thinning pays. It will also pay with pears, and especially early apples, to the production of which fruit-growers should give more attention.

Strawberries.—See that the pickers do not mix over-ripe berries with those to be sent to market. While the berries at the top of the basket may be turned to show the best side, the fruit should be the same all through.

Currants, when nearly full-grown, in some markets, bring a higher price than when ripe. If green currants are marketed, thin the crop so that that which is left to ripen, may be benefited.

Gooseberries are generally sold green. Look out for the worm on both these and currants, and use White Hellebore, a tablespoonful of the powder in a pailful of water. Apply with a syringe or garden engine.

Tents which the insects pitch in the heads of trees, should be removed early in the morning. The hand, with, or without a glove, is the best implement yet invented.

Grape-vines.—Tie up the young shoots. Pinch out the ends, leaving two or three leaves beyond the last bunch. Each shoot usually bears three clusters. If these are reduced to two, or even one, the fruit will be all the finer. The rose-bug is very destructive to the grape—shake it off in early morning, and catch in a pan in which is a little kerosene.

Kitchen and Market Garden.

Weeds are the important crop just now. If they have been allowed to get a foot-hold, cultivators, hoes and other implements must be set at work. If a long, sharp-toothed rake is frequently used between the rows, or wherever there is a bare surface, it will destroy the weeds while they are young, and save much labor—use the rake.

Sowing for Succession is often neglected in private gardens; the season for each vegetable may be prolonged by successive sowings. Beans, peas, corn, beets, etc., etc., may well be sown weekly.

Lima Beans.—If the first planting failed, try again.

Asparagus.—Stop cutting as soon as peas are ready and let the tops grow.

Cabbage and Cauliflower.—Seedlings for the late crop should be thinned, to get strong plants.

Cucumbers for pickles do best when the soil is well warmed—the middle or last of the month is soon enough.

Squashes.—Plant the winter sorts in highly manured rows, made ten feet apart, dropping a dozen seeds every four feet, ultimately thinning out the plants to two. As soon as the plants appear, dust them heavily with plaster, or a mixture of plaster and ashes, and if rains wash it off, repeat it, until the plants are strong enough to resist insects.

Rhubarb.—Keep the flower stalks cut away as they appear.

Sweet Potatoes may be planted during this month, according to directions given elsewhere.

Tomatoes.—Continue to tie to the trellis. Cut away all the badly-formed fruit, and look out for "the worm," which may be detected by its droppings on the ground below.

Herbs.—Thin freely, especially with root-crops. One well-grown carrot, salsify, etc., is worth more than three or four starved, spindling roots.... Provide a seed-bed of sage, thyme and other "seasonable" herbs, from which to draw plants to occupy ground cleared of other crops.... If celery plants get large, cut off the tops to make them stocky.... Store sashes, straw-mats, and similar appliances under cover. Especially use the rake freely to destroy young weeds in the garden.

Greenhouse and Window Garden.

It is generally desirable to remove the plants from the windows, but those in the greenhouse, as a rule, can be better cared for by shading and watering, than if they are taken outside. Plants in pots set outside for the summer, should have partial shade. Set the pots on coal ashes, to keep the worms from entering. The roots are often much injured if the sun falls upon the pots; this may be prevented by setting a board on edge to shade them. Many fuchsias and cactuses bloom only in summer; the best place for these is on the veranda. Hanging baskets are best watered by plunging them in a pail or tub of water, until the earth is well soaked through. Boxes upon the outside of the windows should not be allowed to get dry. Unless the surface of the soil is all covered by the plants, it is well to cover it with moss, such as is found at the bases of trees in the woods. All repairs to the green-houses or the heating apparatus, should be made during summer, and the earlier the better.

The Clover Crop.

Red Clover (*Trifolium pratense*) is the most valuable of all forage plants, but is not suited to wet land. When cut in full blossom and well cured, it is excellent feed for work horses, but if badly cured, dusty, and unripe, it should never be fed to them.

As a renovator for the soil, there is no crop equal to clover. It makes the best food for cattle and sheep, and their young, including colts, and will add greatly to the value of the manure-pile. Clover is the easiest to start, and more certain of producing a crop than any grass. There need never be any failure, if the ground is properly prepared, and the young plants are not choked out by an overshadowing and exhaustive crop of grain. A large variety of clover is best where enriching the land is a main object in growing the crop, as it will afford more stalks and a larger amount of vegetation to decay. It does not make hay of as good quality as the medium or smaller varieties, being so much coarser, and on strong land it is liable to fall and become matted, so that cutting it with either scythe or machine is difficult. The smaller varieties will produce two crops of hay of superior quality in one season. The Alsike or Swedish clover (*Trifolium hybridum*) is a variety between the Red (*T. pratense*), and the White (*T. repens*), with scarlet blossoms, and will ripen its seed and renew itself if allowed to do so. It has no merit over the red clover as a forage plant.

The Flower Garden and Lawn.

The rule to mow the lawn once a week should not be followed blindly. In a dry time, when grass grows but little, mowing should be suspended. Be governed by the condition of the grass. As shrubs and herbaceous perennial plants pass out of flower, cut away the faded clusters, unless it is desirable to save seeds, when a few may be left for that purpose. Roses have many enemies; the slug may be treated with White Hellebore, and the rose-bug may be shaken off and caught, while torpid in early morning. When the leaves of hyacinths and other spring bulbs begin to fade, lift the bulbs, and when dried, store in a cool dry place for fall planting. Continue to transplant annuals, and to set out summer bulbs, such as gladioluses, tuberoses, etc. Give stakes to dahlias, and all other plants that need support. Ornamental beds, or ribbon lines, need attention to keep the kinds distinctly marked. Cut back the plants that trespass on their neighbors. Sow annuals for succession. Do not forget the "Everlastings," always so much in demand for Christmas and other winter decorations.

Bones on the Farm.

It is well enough known that bone, when ground fine, makes one of the best and cheapest manures, especially on lands long in use. The needs of farmers with abundant capital are well enough met in the commercial fertilizers. With the Experiment Stations to analyze the samples, there is not much danger of adulteration. The high price of this comminuted bone, two cents a pound and upward, deters many farmers from using it on a large scale, even where there is no doubt that the investment would pay. In a limited way, the small farmer has the means within his reach, of reducing several barrels of bone to a fine powder every year. A solution of potash will reduce bone to a fine condition, and make it available for plant food. Most farmers still use wood for fuel, and the ashes from the fifteen or twenty cords used in a year, if saved, would reduce all the bones ordinarily within reach of the farmer. The old-fashioned leach that used to stand at almost every farmer's back door for soap making, was a good contrivance for reducing the bones. But any tight, strong cask or box, will answer quite as well for this purpose. Water poured upon the ashes makes a lye, or solution of potash, strong enough to decompose the bones. The casks should stand under cover, so that the quantity of water applied to the bone and ashes, may be under control. The time it will take to reduce the bone to a powder, will depend upon the amount of potash in the ashes, and attention bestowed upon the process. It is essential that the ashes and bone should be closely packed in the mass, and that they be kept in a moist state, adding water as it evaporates from the surface. The finer the bone before it is packed in the ashes, the sooner will it be reduced. The process can be hastened by putting into the mass a few pounds of common potash. But this is only necessary to save time. Ashes from hickory, or any of the hard woods, contain sufficient potash to decompose the bone. When the mass is soft enough to break down with a spade or shovel, it can be mixed with land plaster, dried peat, or loam, to make it convenient for handling. It is a concentrated fertilizer, to be used with discretion in the hill, or applied as a top-dressing to growing crops in the garden or field. We are quite sure that any one who uses this preparation of bone and wood ashes, and sees the vigorous push it gives to garden and other crops, will be likely to continue it. But many farmers near seaports and railroad stations, use coal mainly for fuel, and will have to resort to a hand or horse-mill to use up the waste bones. Small mills are extensively used by poultry men, for crushing oyster shells as well as bone, and the machinery can be adjusted to break the bone coarsely for hen feed. The oil and gelatine of the bones have an alimentary value, and, turned into eggs, pay much better than when used as a fertilizer for the soil.

Treatment of Scab in Sheep.

HENRY STEWART.

The prevalent disease everywhere known as scab, is at times troublesome to western sheep men, whose flocks run on the range, and the universal tick is here, as elsewhere, a great annoyance. As a remedy for these pests, it is usual to dip the sheep. A system of yards and pens is laid out for the easy handling of the sheep, and these all lead

from a large enclosure outside. It opens towards B. The gate C, being open, the yards are filled in succession, the central one and the first one being last filled. At V are boilers and store vats, S, filled with hot liquid to supply the vat D. All being in readiness, four sheep are put into the decoy pens, P, P; these have wire fences so that they are plainly seen by the other sheep. The first pen is then opened and the sheep run towards the decoys, where they stand on a drop or tilting stage, made between the decoy pens. This stage holds ten to

or with its nature otherwise changed, a correct account of its value may be kept by reckoning it at the market price at the time.

A crop should be charged with the following items: Plowing of the land; preparing land for seed; fertilizers; value of seed; cost of seeding; after cultivation, if any; harvesting; marketing; interest on value of land occupied, or rent; tax, unless rent includes tax; interest on stock, machinery, implements, etc.; repairs, and wear and tear on implements, machinery, etc.; insurance. The items will vary slightly with each crop. All labor should be estimated at what it costs, or what it would cost if laborers were hired. The value of seed and land, tax, rent, interest on land, implements, buildings, etc., and many other items may be definitely computed. Some items must be estimated approximately, but a substantial degree of accuracy may be attained. A farmer can make a pretty close estimate of the number of acres a plow usually turns before it wears out. Dividing the cost of the plow now in use by this number of acres, will

Fig. 1.—YARDS AND PENS FOR DIPPING LARGE NUMBERS OF SHEEP.

Drawn and Engraved for the American Agriculturist.

to a point where a dipping vat is provided, to which are annexed, boilers for heating the dipping fluid, and draining pens for collecting the dripping from the dipped sheep. A plan of the yards and pens is shown in figure 1, and another, which may be more suitable in some cases, in figure 2. The former plan is laid out as follows: The large yard, marked 1, tapers gradually to a lane, 2, guarded by a gate, 3, which swings either way to turn the sheep into the pens 4, or 5, as may be desired. This plan is devised so as to be made available at shearing time, when the sheep are turned into the pen 5, which has a boarded floor, that it may be swept and keep the sheep clean, and from which they may be taken into the shearing yard or shed marked 6. This arrangement thus serves both purposes, and every rancho where more than a thousand head are kept, should be provided with something of this kind. It is always best to dip the sheep immediately after shearing, as the dip then has more effect upon the skin; but a dipping should have been given two weeks previously, to cleanse the wool from the mites, which would otherwise infest the yards and pens, and make them a constant source of infection. The yard, 4, is intended for the lambs, which are thus spared a good deal of injurious crowding among the sheep. From pen 5, pens 7 and 8 are filled, and as the sheep are crowded to the narrow part of the pen, a man takes one by one and drops them into the vat 9. Each sheep is completely immersed in the dip, and is guided by a shepherd by means of a crook, back and forth, so as to force it to remain until the wool is saturated with the medicated fluid. When the sheep has been guided up to the bar 10, it is pushed completely under the surface, and under the bar, where it reaches a sloping barred floor, 11, up which it passes on to the draining floor, 12. The work thus proceeds until this floor is filled, when the sheep are passed into the next one, 13. The floors of these pens slope a little, so as to carry the drip from the wool back into the vats, and prevent waste. The temperature of the liquid in the vats is kept up by means of a supply in a boiler near by, from which hot liquor is dipped as it may be required. When pen 13 is filled, the sheep are then dry, and are turned loose through the gate into the open ground. The pens on either side of the lane 2, are intended for lambs which are able to escape through the bars of the fence. The other plan, figure 2, consists of two circular fences, the space enclosed between them being divided into pens by cross fences and gates. The entrance gate, A, opens from a long tapering lane, into which the sheep can easily be driven

twelve sheep, and they are thus plunged into the dip and completely immersed. They are guided to the sloping floor at the other end of the vat, from which they are turned into the draining yards, each of which is filled alternately, thus giving ample time for the sheep to dry, before they are turned out. This is necessary, as the sheep have lambs at this time, and the dip is not very agreeable to the lambs. When both yards are filled, the first one is emptied and immediately filled again, while the sheep in the other are draining. The dip consists of an infusion of tobacco, mixed with sulphur.

The Cost of Crops.—Keep Accounts.

Not one farmer in five hundred keeps books of accounts. No other class of men with the same amount of capital conducts business at such loose ends, and is one of the modern wonders that farmers do not all become bankrupt. It shows how sure and safe farming is, for we should expect nothing less than failure on the part of the mer-

Fig. 2.—A SECOND METHOD OF SHEEP DIPPING.

chant or banker who kept no accounts. Without accounts, the farmer can know but little about his business. He can not tell what a single crop costs or what he realizes for it, which crop pays and which does not, what class of farm-stock is to him profitable or otherwise, or what field has brought in more than has been expended upon it.

He does not keep accounts, because he thinks the work too difficult, but it is not necessary for the farmer to be an expert accountant. If possessed of only average intelligence, a fair supply of good common sense, a blank book and a pen, he can do all that is essential. The transactions of each day can be set down at night in a few minutes. Among the leading advantages of book-keeping is an accurate knowledge of the cost of each crop. When sold as harvested, the amount to be credited to a crop is easily determined. When fed to stock,

give in cents the wear and tear of a plow per acre. Multiplying this by the number of acres in each case will determine the amount to be charged in this item against each particular crop. In the same way the wear and tear of other implements can be determined. The work may be made to include this item. Thus, the farmer may get three dollars per day for every day he plows for others. Then multiplying the number of days employed in plowing for a certain crop by three dollars, will include in the product labor, interest on implement and stock, wear and tear of same, etc. For so much per acre, the man with a self-binder will cut and bind your wheat. This again will include several items in the cost of harvesting.

Wear and tear of land and value of fertilizers must be approximated, and are both considered together. The cost of fertilizers is a matter of certainty, but the amount to be charged against the crop to which they are applied is not, for it will not appropriate all of them. If the fertility of the land is maintained by the use of fertilizers, nothing for wear and tear of land should be held against the crop, for it is charged with the cost of the fertilizers. It is apparent that the amount to be charged in this item each farmer must determine for himself, for it will depend upon the character and quantity of the fertilizer, whether it has been applied to that crop, or the preceding one. Yet, with a little thought, the farmer can estimate these very correctly. If part of the crop is reduced to manure, the value of this should be credited to it.

Encourage the Birds.

War is being waged by farmers against all birds, except a few popular songsters, and most boys are taught that birds and birds' nests are their rightful prey. These little creatures do some damage it must be admitted. They will pick up seed that has not been well covered, but that ought to teach the farmer to sow his seeds more carefully. They will feast upon the ripe grain, and sometimes destroy more than they eat; but the farmer seldom considers that he might not have had any grain to harvest, were it not for these same feathered intruders. During the time between sowing and harvesting, birds must live upon something besides grain, and I fancy that farmers seldom think that that something is principally insects, and the eggs of insects. They rear their young on these, and one can hardly estimate the immense number of insects thus destroyed. Were it not for this safeguard that nature has kindly furnished us in the form of the feathered race, the world would, according to the best calculations, be completely overrun in a few years of uninterrupted propagation, with crawling, stinging pests. Birds have an important work to do, and

we should aid them with all the means at our command; certainly we cannot afford to destroy our protectors. Every farmer should teach his children to cherish and protect their feathered friends. Encourage the birds, and children too, by building bird-houses about the farm buildings. Teach the boys to build these houses, and thus serve two purposes at once—accustoming them to the use of tools, and imbuing their minds with humane sentiments. Many a farm home knows naught of music, but that which floats on the air from nature's own orchestra. Let us have all the sweet sounds we can, to soften and lighten our rural toils.

W. D. BOYNTON.

Farm Gates.

Farmers lose enough time letting down and putting up bars to pay their taxes, if profitably expended. I would have many gates upon the farm. They are inexpensive, convenient, and should be wherever there will be any use for them. When I see a farm well supplied with gates, I know that man is progressive and making money, for he values time, and wisely seeks to save it.

In these days of self-binders the gate-ways should be at least fourteen feet wide. I have found the best material for a gate to be pine boards, and seasoned white oak for end pieces. All the wood used in the construction of the gate should be well seasoned. It is best to plane all the wood-work, though this is not absolutely necessary. Cover each tenon with thick paint before it is placed in

attempted. The only right way to brace a gate is shown in fig. 5. The gate may be further strengthened as shown in fig. 6. Before the gate can sag, the brace must be shortened; for as the gate settles, the points *a* and *b* must come closer together, and this the brace effectually prevents.

The posts should be set in such a way that they will not be pulled to one side and allow the gate to sag. The post must be put below the line of frost, or else it will be heaved out of position; I would say that three feet in the ground was none too deep. Have a large post and make a big hole for it. Be careful to set the post plumb, and stamp the

Fig. 7.

Fig. 8.

Fig. 9.

earth firmly in the hole—it can not be stamped too hard. While stamping, keep walking around the post so that the earth will be firmed on all sides. Blocks may be arranged as shown in fig. 7; but I do not consider this necessary when the post has been rightly set, although it may be advisable to take this further precaution.

To remove the pulling weight of the gate when closed, the swinging end may rest upon a block;

needs no explanation. By sliding the gate back until it almost balances, it may be carried around with ease. In fig. 12 the fastening, or latch, must be so arranged as to hold the lower part of the gate in position. The box of stones renders it easier to move the gate. A heavy block of wood serves the same purpose.

JOHN M. STAHL.

Prolong the Milking Season of Cows.

It is well known that there is much difference in the length of time cows continue in milk in the

same herd, and with the same treatment. Some cows give milk but seven months, while others continue nine or ten months. This difference is mainly a matter of breed and of training during the first season of the heifer's milking. The Jerseys and their grades are generally better fed and run easily from the start, into a long milking season, not infrequently up to the time of calving, where this is desired. But in any breed the season may be prolonged by the care of the heifer with her first calf, and during the first milking season. She should be kept in good condition all through the months of pregnancy, and, if practicable, drop her calf in the fall, when the barns are full and there is an abundant store of milk-producing food. With good hay, and regular rations of roots and meal, and kind treatment, the habit of giving milk through the winter may be thoroughly established. In a family cow this habit adds much to her value.

Fuchsias—Training and Management.

JAMES SHEEHAN, GENEVA, N. Y.

We confess to have a special liking for the Fuchsias, and think no assortment of house plants is complete without one or two varieties of these

its mortise. The gate itself should be painted. Have everything fit tightly. Fasten the brace to the cross-pieces with small bolts or wrought nails well clinched. Mortise the ends of the cross-pieces into the end posts, and secure them in place with wooden pins wedged at both ends, or iron bolts. The best cross-pieces are made of pine fencing-boards six inches wide; the end pieces should be four by seven-inch scantling, although the one at the latch may be lighter. Five cross-pieces are enough. The lighter the gate in proportion to strength, the better it is. There is but one right way to brace a gate, and many wrong ones. The object of bracing is to strengthen the gate, and also to prevent its sagging. Gates sag in two ways; by the moving to one side of the posts upon which the gates are hung, and the settling of the gates themselves. Unless braced, the only thing to hold the gate square is the perfect rigidity of the tenons in the mortises; but the weight of the gate will loosen these and allow the end of the gate opposite the hinges to sag. It is plain that a brace placed like that shown in fig. 1 will not prevent this settling down. The only opposition it can give is the resistance of the nails; and these will draw loose in the holes as readily as the tenons in the mortises. A brace set as shown in fig. 2 is not much better,

or a pin inserted in the end piece of the gate may rest in a slot sawed in the post, or on a shoulder of the post. Fig. 8 shows one end of a combination of two plans—the iron rod from near the top of the high post holds the gate, while the strain upon the post is lessened by the opposite end of the closed gate being supported on the other post.

For hanging the gate I have found the best

Fig. 10.

Fig. 11.

Fig. 12.

hinges to be those shown in fig. 9. One part passes through the end-piece of the gate, and is secured by a nut on the end. The other piece is heated and driven into the post, following the path of a small auger-hole. Next to this I rank the strap hinge, which should be fastened with bolts or screws. Three easy, cheap ways of supporting the

beautiful flowers. They are easily propagated, either from cuttings or by layers, and the amount of bloom one strong, healthy plant is capable of producing under favorable circumstances, is truly wonderful. Upon one plant of *Fuchsia speciosa* started from a cutting of a single eye in March, we counted at one time in the December following, one hundred and fifty perfect blossoms. The plant stood in an eight-inch pot, and measured four feet in height. Some kinds do better as house plants than others. Among the best are *F. speciosa*, *F. fulgens*, and the Rose of Castile; and I would particularly recommend these sorts as superior to all others for the window garden. The right kind of soil has everything to do with success in growing fine Fuchsias; it should be of a light, peaty quality, with one-third cow manure, all thoroughly mixed together until well decayed. They also relish an abundance of water while growing, and once or twice a week an application of liquid manure will be beneficial.

While growing, never allow the roots to become pot-bound, but when the roots begin to form a mat on the outside of the ball of earth, it is time to

Fig. 4.

Fig. 5.

Fig. 6.

as the resistance must depend upon the rigidity of the upright piece in the middle, and the nails or bolts holding it will give way enough to allow the gate to sag. The method shown in fig. 3 is fully as faulty, while the form shown in fig. 4 is even worse. It seems strange that any one should brace a gate in these ways, but I have quite frequently seen it

gate are shown in figs. 10, 11 and 12. In fig. 10 a stout band of wood, or one of iron, may be used in place of the chain. And in place of the stool for the reception of the lower end of the end-piece, a block resting on the ground, or a shoulder on the post, may be substituted. The mode shown in fig. 11 is common in the West. Its construction

shift the plant into a pot of the next larger size, and so on as the plant may require it. This is a very important point, and should not be overlooked if strong, healthy plants are expected. Fuchsias are especially desirable for training on trellises. They can be trained over an upright trellis, and have a very pretty effect, but the best form is that of an umbrella. Secure a strong, vigorous plant and allow one shoot to grow upright until about two feet high, then pinch off the top of the shoot. It will branch out and form a head, each shoot of which, when sufficiently long, may have a fine thread or hair-wire attached to the tip, by which to draw it downward; fasten the other end of the wire or thread to the stem of the plant, and all the shoots will then be pendant. When each of these branches has attained a length of eight inches, pinch off the tip, and the whole will form a dense head resembling an umbrella in shape; and the graceful flowers pendant from each shoot will be handsome indeed. Remember to keep the stock clear of side-shoots, in order to throw the growth into the head.

If properly taken care of, most Fuchsias will bloom the year round; but some kinds can be especially recommended for winter blooming; among them are: *F. speciosa*, flesh-colored, with scarlet corolla; *F. serratifolia*, orange, scarlet corolla, greenish sepals; Meteor, deep-red corolla, light-pink sepals. The following are the finest in every respect that the market affords. Mrs. Bennett, pink; Sir Colin Campbell, double-blue; Rose of Castile, single-violet; Elm City, double-scarlet; Carl Holt, crimson; Tower of London, double-blue; Wave of Life, foliage yellow, corolla violet; *F. speciosa*, single, flesh-colored; and *F. fulgens*, long red corolla.

Cucumbers for Pickles.

The pickle crop is a fairly profitable one if there are pickle factories within easy reach. The seed is sown in the first half of the present month. A light, warm, and rich soil is needed. The ground may be marked off, four feet apart each way, and hills made where the marks intersect. A common method is to sow the seeds in drills. The whole field is heavily manured, and the seed sown in drills five feet apart, or furrows are opened, the manure distributed liberally in them and well worked in with the soil. The earth is then thrown back over the manure and the surface rolled. At least half a dozen seeds to the foot are then dropped in a slight furrow made by a marker, and covered about an inch deep, pressing the soil with a light roller or the blade of the hoe. Insect pests will appear as soon as the young plants are up, and the latter, from the first, must be copiously dusted with plaster or a mixture of ashes or plaster. Those who live near the coast prefer air-slaked shell-lime for this purpose. The dusting with either material should be done in early morning while the dew is on, and be kept up until the vines begin to run. The plants should be gradually thinned and finally leave one strong one at every foot in the row. When the vines begin to bear, the cucumbers should be picked daily or every other day, and of the size in demand. A barrel holds about five thousand small cucumbers, and from twelve to fifteen hundred large ones. Always cut the cucumbers, leaving them with a stem.

Rye for Hay.

Mr. "A. G. W.," Manchester, Tenn., writes us: You ask for experience in using rye for hay. I cut it in bloom. The heads even then are sweeter than the straw, and horses will pick it over for the former and waste the latter unless cut. When cut and fed to cows giving milk I find it equal to the best Timothy hay, and with me either makes more milk than clover hay.—Rye is better to seed down with than oats, I believe, otherwise oats would be preferable, as nothing else makes so good hay as oats cut just as the most forward heads are in bloom. I have tried both.—For a sowed crop to make hay Hungarian grass is next to oats.

Improved Hives and Fixtures.

W. Z. HUTCHINSON.

Since its invention, the movable-comb hive has undergone a vast amount of modification. At present, however, the majority of bee-keepers have laid aside the supposed improvements and adopted the original frame, and many of them the original style of hive, as given to the world years ago, by that prince of apiarists, the Rev. L. L. Langstroth. The standard Langstroth's frame is nine and one-eighth inches deep, and seventeen and three-eighths inches long; and the standard hive shown at *a* in the engraving, is simply a box with rabbets on the inside of the upper edges of the end pieces upon which to hang the frame. The space between the frames and the inside of the hive is three-eighths of an inch.

A cheap and excellent stand for hives is simply a shallow box, without top or bottom, made from cheap lumber. It should be the same size as the bottom board of the hive, and four inches is of sufficient height. Such a stand is shown at *b*.

Many devices have been employed to enlarge or contract the entrance to a hive, but there is nothing more simple and effectual than triangular blocks, as shown at *c*. They are sawed from inch boards, and are large enough to completely close the entrance when placed in front of it. By moving them apart the entrance is opened; while their shape is such as to guide the bees into the entrance, even though it should be nearly closed. When robber bees are troublesome, the entrance may be easily made so small that only a single bee can pass, while during the height of the honey-harvest the blocks can be entirely removed.

In a previous article it was mentioned that some bee-keepers used queen-excluding honey-boards

A STANDARD HIVE.

between the brood and surplus departments to prevent the queen from entering and depositing eggs in the section boxes. The edge of such a board can be seen at *d*.

Many bee-keepers are discarding wide frames for holding sections, and adopting what is called the "Heddon Case": This is simply a box without top or bottom, one-fourth of an inch deeper than the height of the sections, with wooden partitions inside between the rows of sections. Two of these cases are shown in position at *e, e*, and the position of the wooden partitions will be readily understood by noticing the heads of the nails that hold them in place. To support the sections, a strip of tin, one fourth of an inch wider than the thickness of one of the partitions, is nailed to the lower edge of each partition, and a similar strip to the lower edge of each end piece of the case. The top to the hive, which is simply a board with wide cleats nailed to its ends, is used to cover the cases of sections.

Each case contains thirty-two sections, four and a quarter by nine and a quarter inches square, and an inch and a half wide. When the sections in the case, first set upon the hive, are one-half finished, the case is raised and another case of sections placed between this and the hive. When the sections last set on are partly finished, another case is set between them and the hive. When the sections in the upper case are finished, the case is taken off and the sections removed. In brief, the empty sections are put on at the bottom, and the finished ones taken off at the top. This is the "tiering up" plan, the best with which the writer is acquainted.

SHADE FOR HIVES:—To secure the best results, hives should be shaded in the middle of the day during the hot weather. To accomplish this, the writer uses a "shade-board," two by three feet in size, made by nailing the butts of shingles to a strip of board four inches wide and two feet long. This board, which is shown at *f*, is placed upon the hive with one edge even with the north side of the hive, and the other projecting beyond and shading the hive in the middle of the day. This allows the sun to strike the hive in the morning and evening. The board is kept in place by a stone.

Among the Farmers.—NEW SERIES, No. 2.

BY ONE OF THEM.

I have been "knocking about" a good deal among the farmers the past month, and have seen things to make me open my eyes. They have not been by any means closed along back, but one can never see so much when pursuing the even tenor of his daily life, as when "on the go." This time I have been among the so-called

"Gentlemen Farmers,"

men who make, in a measure, farming a pastime, who live in town during the winter, or who having other ways of getting money, spend it upon the farm, with little care whether it pays in money or not. They are paid, no doubt, over and again in pleasure, even if their milk and champagne, if they drink either, cost them the same price. I have often said, that I knew no happier men than those who have a good business wherewith to earn their money, and a fine farm to spend it upon.

I would by no means say that "Gentlemen Farmers" do not make farming pay. Many do. Not pure and simple farming perhaps, but farming in their way. A successful merchant ordinarily makes a good farmer. So he is just the man to enjoy a farm. A man who can keep a hundred milch cows, and make butter all winter that sells at fifty-five to sixty cents a pound, or one who can sell his heifer calves at an average of three hundred dollars each, and half his bulls at a third of that, has merchant enough in his make up to be satisfied. There are horse farms that pay; sheep farms that pay; fruit farms that pay; poultry farms that pay very well, and a good many milk farms that pay.

Jersey Tests.

The tide of popular favor is setting so strongly in favor of Jersey cows, and their merits are being so rapidly developed, that it is no wonder that they are the favorites among the people to whom I allude. The Jerseys have been valued and enjoyed for their beauty and for their elegant product—firm and abundant butter, but now the excitement of training them for, and conducting their tests is added. As it requires great care, the taking of no small risks, and very considerable expense withal, it is essential that these tests should be undertaken by rich men, and not by men rich only in houses and lands and fine cattle, but in character, and a reputation for accurate, conscientious honesty, which is worth more even to a poor man than all material wealth.

The reader may wonder why a cow that makes twenty pounds of butter in a week, ought to be the property of a rich man, rather than of a poor one. I will tell them at the risk of letting out a secret. Such a cow, when put to her best butter-making pace, must be fed and handled without the least regard to expense. The question is, first, how

much can she be made to eat? Princess 2d "beat the record" as a feeder, as well as a yielder in a week's test. She ate one hundred and forty-two pounds, all told, of clover hay, roots, bran, oats, Indian and oil-meal daily, in order to make her twenty-seven pounds and odd ounces of marketable butter. She cost her owner four thousand eight hundred dollars, and as such cows are selling now, was worth at the beginning of the test, at least six thousand dollars. As a race-horse is often disabled in a race, or in training for one, such a test is too often fatal to the cow from the after effects. In this case, by the mistaken kindness of a visitor to the stable, who fed Princess some apples, she nearly died during a sharp attack of colic. These risks must be taken—guarded against if possible—but the results involve the hazard. In regard to this cow, her wonderful constitution, and recuperative power, is shown by the fact that the very day of the colic, she gave three pounds of butter against four and a fraction on preceding and subsequent days. Mercedes, the so-called Holstein cow, that made that wonderful test last summer, is dead, doubtless from indiscrete handling after her test. So is Nancy Lee, a famous Jersey cow.

It is fair to say, their owners sustain a loss of hardly less than ten thousand dollars each, and it is to guard against such results that these cows must be surrounded with every appliance in the stable and out of it, that can promote their health and comfort, while their attendants must be men of great discretion and trustworthiness—fearless feeders, but of good judgment. Such men are hard to find, and when found are worth good wages, and get them. Men in charge of such cows, must have their employers' interests so sincerely at heart, as to be practically incorruptible, for there is no telling what temptations may be presented to them. It is unsafe for a dishonest man to have anything to do with the test of a great cow for butter; he is liable to deceive even himself, as well as his employer and the public. Such a man is quickly found out as a rule, so that on the whole, I think there is reason to place full faith in the astonishing tests which are now from time reported. There is not one of them so far, which has not received and borne well, the severest scrutiny.

Sweet Stables.

I saw Mary Anne, of St. Lambert, a few weeks ago, as it happened, the very day of the completion of the three hundred and ten days, during which she has made eight hundred and thirty-eight pounds eleven and a quarter ounces of marketable butter, and she and her kindred certainly stand in the sweetest cow stable I ever was in. It is made so, I think, by the daily application of air-slaked lime to the floors and passage-ways, in front of, and behind the cows, forming a complete coating to those parts of the stable, not unlike thick white-wash. The floors of the stalls, and the gutters behind them, are not thus treated. Just enough dust arises from this application, to purify the air, while it is otherwise imperceptible, except when the floor is swept, or fresh lime scattered on. It seems to be an excellent plan. No damage comes to the manure, for scarcely any lime comes in contact with it.

When visiting the farms of Messrs. Burnham and McCready, famous for the cows of the Coomassie family of Jerseys, I saw a barn very well altered over. An old barn with its big floor open to the ridge pole, and rows of stalls on one or both sides, is a cold place for fine cows in full milk, during our severe winters. In fact, cows will not stay in full milk long, no matter how well fed in such a place. What is needed is warmth and ventilation. Mr. McCready secured this by boarding up the sides of the hay bays, and putting a ceiling over the floor, allowing plenty of room for a load of hay to be driven in. In this ceiling are three doors that will slide over one another, to give ventilation, and may be easily lifted off when getting in hay. The space which they cover is large enough to give plenty of room to unload, and the result, with double siding, was a most comfortable cow barn, fit for twenty-pound Jerseys. The cows were very hard to beat, and have kept up their flow of milk and yield of butter, as if it had been warm weather.

The Narrow-Leaved Laurel—Lamb-kill.

In January last (page 22) we gave a description of a plant so poisonous to calves, that in some localities it is known as "Kill-calf." Some of our correspondents have confounded that shrub (*Leucothoe racemosa*), with another, which has long been known as poisonous to sheep, and properly called Lamb-kill, and Sheep Laurel. By comparing the engraving given in January, with the one here presented, the differences between the two shrubs will be seen at a glance. The Lamb-kill is *Kalmia angustifolia*, and belongs to the same genus with the showy Mountain Laurel (*K. latifolia*), but is a much smaller shrub, rarely growing over two feet high. It has a wide range, being common on hill-

THE LAMB-KILL (*Kalmia angustifolia*).

sides, and in rocky pastures, from Canada to the Carolinas. Its long, narrow leaves are opposite, or in threes, whitish on the lower surface, and pale-green above; the flowers are light-erimson or purplish, and of about the size shown in the engraving. The experiments of Doct. Thomas F. Wood, of North Carolina, given in the *American Agriculturist* in January, 1883, show that the plant is decidedly poisonous to sheep, but the animal with which he experimented would not eat it voluntarily. His observations were made in autumn, when the conditions are quite different from those in spring, the time sheep are usually poisoned. After having had only dry food all winter, they are attracted by the evergreen leaves of the plant, often the only green thing to be seen, and at that time eat enough to poison them, though they may avoid them later, when green food is abundant. Warm milk and molasses given in sufficient quantities to

cause vomiting, is the usual remedy. This Laurel is suspected of yielding poisonous honey; this is a point that bee-keepers should investigate. It seems to be well established that the honey of some related plants produces narcotic effects, and if that afforded by this species is also poisonous, it will furnish another reason for destroying it.

The Sportsman in Camp.

ROBERT BARNWELL ROOSEVELT.

A stove is a convenient thing to have, but not an easy one to carry, if it is not too heavy and does not occupy too much room it is sure to be too dirty after it has once been used. A makeshift can be extemporized wherever flat stones can be had, and will be found infinitely preferable to the ordinary open fire. All that the traveller will have to carry with him, will be two lengths of common stove-pipe, the rest is built at the camping ground, and can be erected in so short a time that the trouble of moving house will not be serious. Having selected the flat stones, lay them up in the shape of a horse-shoe, the sides being about three feet long, and about nine inches apart inside, that is, the fire place will be nine inches wide, or more if desirable. At the further end, the bend of the horse-shoe, the pipe is inserted; it can be held in place by wires to neighboring trees, and a stone placed on top will serve as a damper. All chinks between the stones have to be well filled with clay or mud, or earth banked up against the outside, or what is better yet, the entire affair can be lowered by having a place dug for it. Large flat stones must then be laid over the top and the work is done. One trial will make any person an adept in building it, and it will be found a luxury, that to appreciate, needs only to be tried. This stove can be erected within the tent, if the trench is dug to the outside and covered with boards, and if there is a hole in the top for the escape of smoke; instead of stones sheet-iron may be used for the stove cover.

The angler will often on his lucky days take more fish than he can turn to account, but which he will probably find use for before his trip is over. These can be salted, and of a morning nothing is better than a salted lake trout or blue-fish. Those who have only eaten eel and mackerel, do not know what a salt fish is. Split them, and cut off the head and tail and take out the back bones, bones do no special harm, and are excellent things to buy at twenty cents a pound for the good of trade, but when you are doing your own curing it is as well to leave them out, or keep a separate place for them. Pick the fish, cut to a proper size, in a half barrel or pail, flesh side down, so that whatever of dirt may be in the salt will not get into them, but will remain on the skin. Upon each layer of fish, lay a thin layer of salt, rock salt will answer, or common table salt can be used. Proceed in this way until the fish are all in, or the receptacle is filled, taking care to put enough salt on top to prevent its melting off when it turns to brine and leaving the fish bare so that they will spoil. That is the only risk in the operation; put down in this manner, they will keep in the hottest weather for weeks.

Where the sportsmen intend to remain in one place, the most convenient way of living will be to put up a regular house, either purchased ready to set up with a few bolts, or built by the party out of boards taken for the purpose, if any one is sufficiently skilled in carpentry to direct. Doors and windows are a luxury, although the open tent is considered by some as the more healthy. The "Hoffmire" house, as it is called, is admirably adapted for transportation, and is constructed by persons well acquainted with the necessities of woodsmen. Such extravaganees are the exception, not the rule of "summering" in the wilderness, and it is our general fate to be without them. We must sleep in the tent, must cook at the open fire, fight mosquitoes and black flies as well as we can, without nets to keep them out, must endure wet and cold, and learn to rough it and have a good time with the aid of our own resources. Among the principal of these will be a knowledge of some of the simplest rules of the cuisine.

How I Found my Prairie Home.

R. G. NEWTON.

I cannot say positively whether my own inclinations, or the advice of that kind-hearted old philosopher, long since gone to his home beyond the western skies, caused me in the winter of 188-, to dispose of my home and immovables, and come West. Living in one of the pleasantest villages of Southern New York, with a good little home all paid for, a good trade, and plenty of work, you

Fig. 1.—A PRAIRIE HOUSE WITH HILLSIDE CELLAR.

may ask why I left all this to come out on the prairies. I had worked fifteen years in the dust and noise of a large planing mill, and all I had to show for it was that house and lot, which was bought at the time real estate was booming. My wife and I had denied ourselves many pleasures to get what we had together, and the prospect for coming years was not a pleasing one. We might be spared to live many years, my wages would give us the necessities of life, but little or none for the future, when I might not be able to work. In looking around me, I could find many men that old age was crowding out of the ranks, but they had in their best days been as good mechanics as any of us, and among them all but very few (and they were the ones who had come in when the country was new and the town just started), that had saved anything in their years of toil. After many sleepless nights, I made up my mind to do what so many had done before, break off with everything connected with that kind of life, and on the prairies of the great West start anew. I did so, and here we are.

I left New York State in the winter, and went into the Red River Valley of Dakota, where I had a brother in the hotel business. The next question was, where should I locate? I had a good opportunity to see and talk with parties, who had visited many different parts of the Territory. Just then the Devil's Lake country was having a "boom;" there was the Mouse River country, and many other localities open to settlers, but I wanted to build my future home where I could raise a variety of field crops, corn especially, and not live without

Fig. 2.—CROSS-SECTION OF THE CELLAR.

a garden. I decided to have a look at the country between the Jim River and the Missouri. So in the middle of March, with between two and three feet of snow on the ground, I started. In three days I was in Aberdeen, and passed the last snow-bank in the cuts through the hills in Grant County. At Aberdeen I found the "booming" point was on the Missouri River, but as it necessitated a ride of a hundred miles over the prairies (with one stop-

ping place), in an open or lumber wagon, and during March weather, it was not what I wanted. I went to the Huron district, getting what information I could, started on the road towards Pierre, and stopping at St. Lawrence, found a team just starting north with two young men, who were going up there to locate. Joining them, we rode about forty-five miles almost due north, getting to our destination about seven o'clock. After supper, I made arrangements with a "locator" to be on hand early in the morning with a team, and show me some of the unoccupied land near the town,

which was just starting. After this I was shown to my sleeping-place, which was half of one end of a bunk, twelve feet long, accommodating four, with one just like it built above. Morning came, and getting up, I counted twenty-three lodgers in that room, about eighteen by twenty feet square. When going down stairs, I had to step over two or three persons who were still snoring, under buffalo robes, coats, and any other covering obtainable. After breakfast came

the driver, who took me over several claims; I went back to the hotel, and at nine o'clock, the stage running to the nearest rail road point came up, and off we went. I decided on my way down to enter my filing on the first claim we went over.

I went to Huron Monday, but could not get my filing made out until it was too late to get it in that day, but I was on hand the next morning with many others. I found the piece was not taken, my entry was accepted, and I started again for the North, intending to spend the summer with my

Fig. 3.—FLOOR PLAN OF THE CELLAR.

brother, and come on to my claim in the fall, which, by making a Homestead entry, I was enabled to do.

LOCATING THE HOUSE AND STABLES.

Claim shanties are usually built on the point nearest to the adjoining town, but many other parts of the farm may be much better for building sites. Shelter from the winds, of which those from the north-west are the most prevalent, is very desirable. Locate the house and stables within easy access to water. By digging deep enough, well-water will be reached almost anywhere. If the well is necessarily located some distance from the house, you can erect a wind-mill, lay a few rods of iron pipe and have a steady supply of water at the barn and house.

In Central Dakota the land is sufficiently undulating to afford sometimes a choice of several locations on a quarter section. A rise of the ground of fifteen to twenty-five feet will shut off the heavy winds, and by placing the buildings at the foot or a little way up the rise, and planting the top to evergreens, mixed with other trees, you will not feel the winds at all. The advantages a hillside offers for a cellar are not to be overlooked. By digging down a little way, you can then excavate directly into the hill, making a hall or cutting about four feet wide, and as long as desired. By digging out bins at the side, roots and other crops may be secured from frost. Fig. 1 shows a dwelling, with a cellar dug into a hillside. The

side excavations are at *a, a, a*, and a ventilator, *b*, rises from the main part. Fig. 2 is a cross-section of the underground cellar, *a*, showing the side bins, *b, b*. The floor plan of the cellar is given in fig. 3. The hard subsoil makes such a cellar easily constructed, and by leaving a space of solid earth between each bin of two or three feet, you will not require to use a stone in the whole construction. It will require a good, tight door at the entrance of the gallery from the cellar, and it may be necessary to provide for ventilation, which can be done by digging one or more holes from the top of the hill down into the gallery. Cover the ventilating shaft tightly with a large box, not easily overturned. The top should be built to shed the rain, and holes a foot across cut in the sides and covered with wire cloth, to keep out vermin. If the roof extends over the sides considerably, and the holes are close under the roof, but little rain will beat in. This box can be removed, if necessary, after freezing weather sets in, and a board covered over the hole, with some earth thrown on it to keep it in place, but if there is much thickness of earth over the cellar, it may be better to leave the ventilator open. This cannot be done in many parts of Northern Dakota, as the water would fill the cellar the first winter.

Cider-Making Without a Press—Diffusion.

The method of extracting sugar from the beet root by dissolving it out with water, or diffusion, as it is called, has been applied to cider making in some districts of France. As the method is very simple and is practicable on a small scale, some of our readers may wish to make a trial of it. A cask or keg of any convenient size has a false bottom in which are numerous holes, and is raised a few inches above the real bottom. The apples are ground, and packed in the cask on the false bottom, first placing a coarse cloth over it. At the top of the apples is a follower. Water is poured in sufficient to cover the apples, and the whole allowed to stand for twenty-four or thirty-six hours. At the end of the proper time the liquid is drawn off through a spigot in the cask near the bottom. Water is again added, allowed to stand and drawn off; this is repeated once more, making in all, three diffusions. The resulting liquids are mixed together and treated like new cider made in the usual way. If not rich enough sugar may be added. By this method cider may be made without expense for press or mill, as the latter, though convenient, is not necessary, as the apples may be brought to a pulp by pounding them in a barrel or strong tight box. This process leaves the pomace in better condition than that from the press, whether to feed to the pigs or to add to the manure heap.

Salmon Fresh from Oregon.

The latest immigrant is the Oregon Salmon. There has been inaugurated the past spring a system of shipping in regular cars, the world-famed salmon of the Columbia River, to the Eastern markets. The "Chinook" salmon is a stranger at the East; the "steel-heads," that are not considered choice on the Pacific Coast, are the only salmon from the Western States that have reached eastern markets. The "Chinook" does not commence running until the middle of April. The salmon fisheries of the Columbia River are mammoth enterprises to-day. There are fifty large canneries between Astoria, at the mouth of the Columbia, and the Cascades above Portland. Three average salmon fill four dozen cans, each holding a pound; there are forty-eight cans in a case. When this industry began, in 1866, a case of salmon cost sixteen dollars; to-day, the current price is four dollars. There are two thousand boats, including a dozen steam-tenders, employed in this business alone on the Columbia River. A new impetus will be given to the industry by the new enterprise of shipping the fresh salmon to the Eastern States.

Houdan Fowls.

It is very interesting to see what different styles of fowls the various peoples of the world have produced, no doubt chiefly by selecting those for breeders, which have been for generations regarded as best adapted to their own use or for market. This has doubtless been to some extent influenced by the original stocks which they had to work upon, largely also by climatic influences, but chiefly by the needs, fancy and caprice of the people. Thus the French fowls differ from the English, the Dutch from both; the Spanish and those of the Mediterranean Coast are of a very different type, and so they vary throughout India, China, and Japan. There is often a style and air about the

baek, and these are bound with bandages (that leave no mark), upon a properly formed board to get cold and ready for shipping or exposing on the market stand. They look worth several cents a pound more than if shipped and exposed for sale in the common New York way, which is the way of the greater part of the country, except New England, where fowls are drawn before marketing.

Poultry Keeping as a Business.

We are constantly in receipt of letters like the one below, from persons who, with a very small capital, seek to better their mode of livelihood, and become more independent. Far be it from us to

off by scores. The approved plan is to use very early hatched pullets as layers, and to begin as early as February to kill them off as they stop laying, and to clear the yards before broilers are plenty, and the price of fowls falls very much. Third: As to capital. A good lot of young fowls for winter laying, could hardly be obtained for less than one dollar a head, and those from which one would expect to raise chickens for next year's layers, ought to cost double that. So really the three hundred dollars would not go far, still, if a person has a year or so to get ready in, and can live and work for that time without encroaching on his capital, perhaps a start might be made, even on three hundred dollars. The things to do would be to put up a building for the fowls, light, dry, and warm, half

A HOUDAN HEN.

A HOUDAN COCK.

fowls, which reminds one of some type of character among the people, and this is especially true of the French and Spanish fowls.

We select for illustration one of the best known and most useful French breeds, the Houdan (pronounced *hoodon*—the last syllable like *don* in *don't*). This breed combines three exceedingly useful characteristics. The birds have few if any superiors as table fowls; the eggs are large, white, and abundant, the hens being persistent layers and non-sitters, and the chicks develop very rapidly and are early ready for market as broilers. In point of hardiness and general utility there is difference of opinion, but all agree that they are the hardiest of all the French breeds, both in this country and in England. The idea that they are not hardy comes from the fact, that imported fowls do not acclimate easily if at all, but American bred Houdans appear to be as hardy as any. It is not difficult to get such.

The Houdans are white-skinned fowls, with pinkish or mottled legs, and a useless fifth toe, like the Dorkings. This is no serious objection to them, and is one of the criterions of purity of blood. Our illustrations show the fowls very well. They are above medium size, with black, white, and gray or mixed feathers, evenly but irregularly mingled. They are well formed, full-breasted, have moderate powers of flight, are domestic, but good foragers. They have top-knots of medium size, which do not obscure the sight as do those of the Polish fowls. Their combs are branching, somewhat like the antlers of a stag, and thus help to keep the crest-feathers out of the fowls' eyes.

They will do well with reasonable care in any dry, warm, clean location, and give great satisfaction, being fully equal to the Dorkings for the table, though not so large, and quite as hardy. These fowls, when well fattened by a French poultryer, surpass anything we ever see in our markets. They are drawn, the thighs thrust back beneath the skin, the wings tucked behind the

discourage them, but before undertaking poultry and egg raising as a new business, they should know for certain that they will find it very hard for a time, and may exhaust both themselves and their capital before they get started. Mr. D. J. Quinby, writes from Philadelphia, Pa., as follows:

"I can control about one acre and a half of good grass land in Central New Jersey, with a small barn, dwelling house, and a good well of pure water on it. The land in question slopes to the northwest, and to the south. How many chickens can be raised profitably on an acre and a half of land? Could a person get a moderate living from them, making a business of it? How much money would be required to start a run of dimensions given, including incubators, etc.?—I can raise about three hundred dollars. What stock of fowls do you consider preferable, all things considered?"

In answer to these questions we have to say, first, the profits of poultry raising do not depend so much on raising chickens, as upon the production of eggs. This season is too far advanced to do either this year, but summer or autumn is the proper time to prepare for keeping laying hens, and for a harvest next winter. No one can give an exact answer to your question, but we say in general that thousands of chickens may be raised with proper appliances and care. The matter of profit depends upon so many contingencies, that it is impossible to say whether one hundred or ten thousand could be raised with profit. Second: A thousand laying hens could be kept through the winter on the surface named, and ought to lay thirty eggs each on an average, and these should net the raiser two cents each, which would amount to six thousand dollars. Still though one thousand hens might do very well in winter, keep one another warm, and with care and cleanliness be healthy, yet one hundred and fifty hens would overstock the place in summer. It would be easy enough to raise one thousand chickens, unless they should suffer from some epizootic malady, which might sweep them

underground perhaps, and well banked up with earth in winter; to secure chickens whenever it is possible. You would have to do your own carpenter work, and then a house for two hundred hens would cost you fifty dollars. A winter house for that number of hens, need not be more than twelve by twenty-five feet on the ground, and high enough for a man to stand up in. In close quarters they keep one another warm, and lay better. Fourth: The best fowls for eggs, all things considered, are Leghorns. Probably the best for general purposes are Plymouth Rocks.

The Eatable Podded Peas.

W. B. Jones, Henderson, Ga., writes us with reference to the eatable podded peas, figured and described in April last, that a variety of them has been cultivated in his vicinity for eighty or a hundred years. Besides the names given in the article referred to, it is with him called "salad pea," and "snap pea." Mr. J. gives a method of cultivating these and other peas, avoiding the trouble and expense of "bushing," which will be useful to many others in the Southern States. The peas are sown along the rows of cotton stalks of the growth of the previous year. In the latter part of December, or in January or February, the soil is plowed away from the stalks, running close to them; the manure is distributed in the furrow, and the earth turned back over it. In the bed thus formed, the peas are drilled in, a row on each side of the stalks, and as near them as practicable. The stalks are strong enough to bear the pea vines until the crop is mature. Mr. Jones says that they have their first picking about April 10th, and that the pod is very brittle, snapping off short like a German Wax-bean. The peas are used when young as a salad, and when sufficiently mature, are shelled like ordinary peas. When the crop is allowed to ripen, the stalks and vines are pulled up, and removed to a shelter.

The Creamery and the Farmer.

PROF. S. R. THOMPSON, NEB. AGRICULTURAL COLLEGE.

Among the various ways of diversifying production on the farm, the creamery has many advantages. It yields quick returns. Many creameries pay cash every month. A farmer who lacks capital to stock his farm and must wait for the natural increase to give him his return, may, by investing in cows, get a return in a few months. He thus, in a measure, gets the advantage of the "nimble sixpence." The results are more certain than in most other lines of farming. Good butter is always in demand for cash. The product being sold as fast as made, the risk of a falling market with a full stock on hand is largely removed. If extreme fluctuations in price come, they affect only a part of the year's production. The business is fairly remunerative. The profits, as is usual with a business in which the element of risk is largely removed, are not excessive, but being steady, may in the long run be better for the farmer than a more speculative line of work in which there is a promise of larger profits. In presenting some points connected with the question of profit, I cannot do better than give a statement made to me by Mr. S. C. Bassett, of Buffalo Co., Neb. The figures are taken from his books, and so far as they are an estimate, it is that of an intelligent, cautious, and trustworthy farmer. This is the summary for 1883:

No. of cows milked.....	12
No. of calves raised.....	12
No. of inches of cream.....	2271
Average number of inches per cow.....	189 1/4
1291 inches of cream, @ 16 cts.....	\$206.56
980 " " " @ 20 cts.....	196.00
Total received for cream.....	\$402.56
Per cow.....	\$33.54

It should be stated, that the cows were well fed and cared for in the best manner. Besides hay and grass, each cow was fed sixty-five bushels of corn during the year. The estimated value of the food of one cow was as follows: Pasture in summer, two dollars; hay in winter, three dollars; sixty-five bushels of corn at twenty cents, thirteen dollars. Total, eighteen dollars.

The other sources of income from the cow, besides the cream were the skim-milk and the calf. Mr. Bassett estimates that the skim-milk judiciously fed, would produce or be worth eighteen dollars, and the calf at three days old would bring five dollars. The skim-milk, properly utilized, will therefore pay the cost of feeding the cow, leaving the value of the cream sold, thirty-three dollars and fifty-four cents, and the calf five dollars, or a total of thirty-eight dollars and fifty-four cents, to pay for interest, cost of labor, and net profit.

This it seems ought to be on the whole a satisfactory showing. A farmer who in addition to his other farming operations keeps ten or twelve cows, is able to count on a cash income monthly of something over thirty dollars at the lowest estimate. Farmers who have the requisite skill to make good butter, and who also live near large towns, can often do still better than this, by engaging their product to regular customers, and delivering it as needed. But where there is one farmer who can do this to advantage, there are two or three who could sell cream to a creamery with much greater profit. It would seem that a well managed creamery ought to be of great advantage to any rural community, and the rapid extension of the creamery system throughout the West confirms this view.

It is a great mistake to suppose that any kind of management will produce such results as are indicated above. The following are some of the essential conditions of success in the business of furnishing cream to a creamery: The cows must be liberally fed; valuable production comes from abundant food. There must be the greatest regularity in feeding, watering, and milking the cows. The cows must be good ones. These cannot always be bought, and the successful dairyman should raise his own cows as fast and as far as possible. He can thus be in a position to select the best to keep, and sell the others. The whole husi-

ness must be under the immediate direction and care of the owner, or of some painstaking person who has a pecuniary interest in the returns from the dairy. It will rarely be possible to have the work done successfully by hired help alone.

A Small Poultry House.

Mr. L. E. DeGour, Morristown, Pa., sends us sketches and description of a small poultry house,

Fig. 1.—EXTERIOR OF A SMALL POULTRY HOUSE.

from which the accompanying engravings are made. The house is ten by thirty feet, seven feet high in front, and five feet at the rear. The boards are "common thirds," with lath placed over the cracks. The roof is tin, with two ventilators. The yard for the young chicks has a board floor, to keep them from the damp earth. This house will accommodate seventy-five birds. The materials cost about fifty-three dollars. Mr. DeGour, though

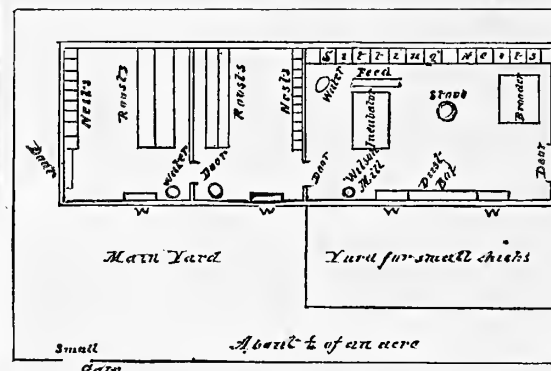

Fig. 2.—GROUND PLAN OF THE POULTRY HOUSE.

not a carpenter, built the structure, and is sure any one at all accustomed to the use of carpenter tools, can do the same from the accompanying plan.

Dairy Questions.

Messrs. Waltz & Wæner, of Montana Ter., ask us several questions on dairy matters. Our answers to some of them will indicate the questions. It takes a little over eight "pounds of milk to make a gallon," and about two gallons of good "milk to make a pound of butter." Yet it will require three or even four gallons of some milk for a pound of butter. It will not pay to make butter, except for your own use, even at sixty cents a gallon, unless indeed you have a sale for sweet skim-milk in some form, at eight to twelve cents a gallon. Jersey cows are generally below medium size, and are no fighters. They would be underlings in a herd of "common ranch cows." They will yield on an average eight or ten quarts of milk a day for six to eight months, and during this time ought to average a pound to a pound and a quarter of butter a day. The "amount of butter made from noted cows," has in some cases exceeded three pounds a day, week after week. It is a very good one that yields fourteen pounds a week. Jersey cows fit to ship, would cost you in the East two hundred and fifty to three hundred dollars each, in carload lots. Orange carrots are better than white, because they help to keep up the color of the butter in winter, and are nearly as productive. Carrots and mangels mixed make excellent food for cows in winter, especially if well sprinkled after slicing with equal parts by weight of bran and corn meal.

Forest Commissions and Agriculture.

The outcome of the protracted discussion in the New York Legislature on the Adirondack question, is a bill which, at this writing, has passed the Senate, and we hope will pass the Assembly. It provides for three Commissioners, to be appointed by the Governor with the advice of the Senate, to hold office respectively two, four, and six years, thus creating a vacancy every two years. They are to take charge of the forest lands now belonging to the State, and of any that may hereafter be acquired; to prevent damage to them by fire, trespass, etc., and to report to the Legislature each year on or before Jan. 15 of their doings, together with such information "as may be useful in preserving the forests upon State lands, and maintaining the supply of water derived therefrom for the use of the State." The bill does not, it will be noticed, provide for an Adirondack Reservation, as did several of those which came up in the early part of the session; but simply for a Commission to care for the forest lands, and for the waters which flow from them.

The main feature in the bill, which makes it desirable to have it passed, is in the clause providing for a report. The annual value of our forest prod-

ucts, according to the last census, was seven hundred million dollars—more than ten times the value of all the gold and silver produced, and more than three times that of the entire mineral output, precious metals, iron, and coal. This enormous total is merely the value of the raw material, and not that of the manufactured articles made out of it, and therefore the lack of forest products means stoppage of these vast industries, all of which create a market for farm produce, and furnish articles needed

for farm use. When we remember that we are rapidly nearing the exhaustion of the greater part of our available supply of forest products, we see that farmers have a very direct interest in forest preservation.

S. W. POWELL.

Short Timber and Wood Supply.

The terrible devastation by the floods in the Valley of the Ohio, the last winter and spring, is a text from which many of our papers are preaching sermons on the waste of our woodlands, and prophesying greater evils in the future. The case is by no means as desperate as the pessimists would have us believe. New England is among the oldest settled portions of the country, and in this section the danger is already passed, if it ever existed, and intelligent observers assure us that there is more woodland to-day, than there was fifty years ago. More than a quarter of the land is in wood. The white pine, one of our most valuable timber trees, may not be so plenty or as large as in the olden time, but it still exists, and furnishes large quantities of lumber, as the shoe trade of Eastern Massachusetts attests. Timber land cleared and left to renew its growth, is ready to clear again in twenty-five or thirty years. And so far as the holding of snow and rain is concerned, it is about as valuable as the original forest. The shade is complete, the leaves and leaf-mould are retained, and floods are no more numerous or destructive than they were in the early settlement of the country. There are two forces steadily operating to conserve our forests, for the most part overlooked by those who prophesy evil from our waning forests. The first is the enormous and steady increase of the production of coal, and the increase of facilities for its distribu-

tion. Steamboats, locomotives, and factories, that once used wood, now use coal almost exclusively. Even farmers within one or two miles of a railroad depot, now use coal and find it cheaper than wood, especially in winter, though the wood grows upon their own farms. And this use of coal is increasing in the rural districts every year, and nothing is likely to prevent its increase in the future. Then the drift of our population away from the rural districts into cities and villages, has an important bearing upon the increase of woodland. The census shows that in the last decade, the exclusively farming towns of Connecticut lost over twelve thousand inhabitants, while there was a steady increase in the cities and villages. This drift is not likely to be arrested by any songs the poets can sing. It means abandoned farms, lone chimney-stacks where farm houses once stood, rocky pastures and meadows turned into thrifty forests. These are a good investment to their present owners, as woodland, the annual growth paying interest and taxes, without outlay for labor. Self-interest is likely to conserve our forests with or without floods. This drift of the population in due time will reach the newer States.

Hanging Nest Boxes.

It is cheaper to construct continuous rows of nest boxes, nailing them securely to the sides of the poultry houses, but they afford a snug retreat for lice, mites, and other insect enemies of fowls, from which it is difficult to dislodge them. By having movable boxes the cleansing process is facilitated, and extreme neatness can be maintained. A good box that is easily made should be from twelve to fourteen inches long, eight to ten inches wide and about eight inches deep, the part by which it hangs being about four or five inches higher. The ends may be made of inch white pine and the front, back, and bottom of half-inch pine, all planed stuff to give a neat finish. A good coat of paint will add to the appearance and go far towards preventing vermin from infesting it, otherwise apply whitewash, inside and out, before nailing. To prevent the back from being broken, securely fasten two inch and a half cleats on the outside. Make two holes, through which the stout screws pass when the box is in place.

A very readily made hanging box is made as follows: The back and bottom are constructed of good, planed inch pine, the height of back being twelve to fourteen inches. The front of the box is made of the sides of a high cheese box, the width (extreme) from back to front being from eight to ten inches. To prevent the front from coming loose where it is fastened to the sides, it should be nailed on with a strip of tin or heavy leather. D. Z. E.

A Wire Splicer.

Mr. A. F. Kemman, New Hampton, Iowa, sends us a description with sketches of his wire splicer. This is an age of wire, as is evident from the net work of wires in the cities, and the millions of miles of barbed wire in fences in the country. To make this splicer, take a bar of half inch, round iron, nine inches long. Heat about three inches of one end and hammer it flat until it is one inch wide. With a cold chisel cut a one-fourth inch slot a quarter of an inch from the right side and an inch deep. Figure 1 shows the slot. Bend the part marked *d*, so it will be a quarter inch from

Figs. 1 and 2.—THE SPLICER.

the flat part, as shown in figure 2 at *c* and *d*. The lower part of the slot *c* should be about a half inch from the bend at *d*. Smooth the parts with a file, thus completing the tool. To use it let *e* and *f*,

figure 3, represent two wires to be joined. Bend the ends so they are nearly at right angles with each other. Hold them with pinchers at *g*; place

Fig. 3.—MAKING THE SPLICE.

the hook of the splicer on the wire *f*, while the wire *e* falls in the slot. Twist the pieces around the wire *f* when one half of the splice is made. Repeat the operation for the other end. Figure 4 represents the splice completed. Use about four or five inches of each wire to twist around the

Fig. 4.—THE SPLICE COMPLETE.

other. This makes a neat, easily made splice for either plain or barbed wire. The splicer is so simple that any blacksmith can quickly make it at very little cost.

Convenient Portable Tool Box.

An old dry goods or shoe box will supply materials, and a little rainy day or evening work will construct a good tool box, very convenient not only for keeping the tools in, but also for carrying them out to the field, for repairing fences, etc. For lightness, use half inch boards for the sides and bottom, and those a little thicker for the ends and handle. The box may be of any size. The following dimensions will admit hand-saws, axes or adz: End pieces eight inches wide, sixteen inches high, tapering from six inches above the bottom to two inches at top. Side pieces six inches wide, thirty-four inches long. Bottom piece six by thirty-two inches. Top piece, or handle, straight-grained pine or spruce, or ash if available, corners rounded. The handle may be nailed in, or fitted to small auger holes and tenoned. Adapt the dimensions to the tools; a common method is, a side compartment, one and a half by thirty-two inches for saw and square; nail-boxes at the ends, with a partition in one of them for an axe blade, the handle to lie along one side. Central portion for hammer, chisels, augers, etc. For a neat job, plane all, and fasten with finishing nails. In such a box the load is balanced; it is easily carried by one man, or between two, each taking hold of one end of the handle. A. F. K.

Shoulder Pads.

Mr. H. C. Blackwood, Washougal, W. T., writes us as follows: I have found a collar-pad made of new, undressed sheep-skin, to be the best preventive of and remedy for sore shoulders in horses. Cut out two pieces about the shape of, and somewhat larger than the faces of the collar. Fasten one edge in the groove opposite the hame groove, with the wool next to the collar. The skin seems to have some healing properties. This pad is quickly and easily made, and is much better than most of the pads sold by the harness makers. One set will last an entire season. I have used these pads a great deal in thrashing, which work is very liable to gall the shoulders of horses, and have found them superior to all other kinds.

Sweet Potatoes in Northern Gardens.

Within a few years, the cultivation of the sweet potato has extended northward, and it is now raised successfully as far north as Central Michigan. Those who wish to undertake its culture on a small scale, will find it cheaper to buy the plants, or sets, than to raise them. In cities the seedsmen offer the plants, and there are several who advertise them. They bear transportation well, and may be sent by mail or express. In Northern localities it is best to raise them on manured ridges. Upon the unbroken surface of the soil distribute well decomposed barn-yard manure in lines, or strips, three feet apart, the manure strips being about a foot wide and three inches thick. With a plow, turn a furrow from both sides, to cover the manure and form a ridge over it. Dress up the ridges with hoe and rake, and plant the potato sets upon the top of it every fifteen inches. If the planting is done in a dry time, make the holes with a trowel, fill them with water, and when this soaks away, set in the plant. If the soil is fairly moist, watering will not be needed. The plants should be set deep in the soil, leaving but one or two leaves above the surface. Should a late frost or an accident destroy the portion above ground, some of the eyes below will start and replace it. The sides of the ridges and the spaces between them should be kept clear of weeds until the growth of the vines covers them. The variety most generally grown at the North is the Nansemond, though there are one or two others for which greater earliness is claimed. When the vines get large, they will throw out roots at each joint; this should be prevented by moving them, by running a rake-handle or some such stick under the vines and lifting them from the earth.

A Convenient Tree-Lifter.

A large percentage of trees transplanted from the forest, die on account of not having a sufficient quantity of roots. The engraving shows a contrivance to aid in lifting trees in good condition. Join at the top two pieces of two by four scantling, four feet long, and nail a cross-piece about six inches from the bottom. Attach a piece of chain, *e*, to one end of a lever, *c*, which is notched at *b*, so as to work on the pieces *d*. To use the lifter, take a crow-bar and punch a hole under the root of the tree to be dug, pull the chain through, and hook it around to form a loop. Cloth or old rags may be

A DEVICE FOR LIFTING TREES.

placed in the loop, to prevent injury to the tree. Cut a circle, *f*, around the tree with a sharp spade. Then let one person pull on the lever *c*, while the other digs. Trees may be very quickly lifted in this manner, and without straining a person as when pulling by hand. The contrivance may be carried by one person. When a large quantity is to be dug, a boy may be sent ahead to make the holes for the chain. JNO. BARTLETT.

A Fence Board Holder.

Figure 1 shows a contrivance for holding fence boards against the posts, at the right distances apart when nailing. A two and a half by two and a half inch piece of the desired length is taken for the upright, *a*. About its center is hinged the brace, *c*. A strap hinge, *b*, or a stout piece of leather for a hinge, will answer. Blocks or stops, *d, d, d, d*, are nailed on the upright *a*, at the required distances, according to the space between the boards on the fence. The bottom boards of the fence are nailed on first. The bottom block of the board holder rests upon the bottom board, and is held in position by the brace *c*. The boards can be placed in the holder like putting up bars, and are guided to their places on the posts by the blocks *d, d*. The boards can now be nailed on the posts, and the holding devices moved for another length. When the boards are too long, they can be pulled forward a little, and

Fig. 1.

the end sawed, and pushed back to place. One man using this contrivance, can nail on nearly as many boards in a day, as two persons with one to hold the boards in the old way. Figure 2 shows the manner of using the fence board holders.

Fig. 2.

the end sawed, and pushed back to place. One man using this contrivance, can nail on nearly as many boards in a day, as two persons with one to hold the boards in the old way. Figure 2 shows the manner of using the fence board holders.

Animal Ailments.

DR. D. D. SLADE.

SHORTENING OF THE TENDONS.—Mr. A. N. Brainard, Carbondale, Ills.—The shortening of the tendons, or cords in the legs of the horse, is due to previous inflammation in the parts, the result of strain and over-exertion.—In the early stages, a long period of rest at pasture with an occasional blistering, may serve to restore the tissues to their natural condition, if they have not been too seriously injured. A high-heeled shoe may facilitate the cure, by throwing the tendons into a state of relaxation. After the tendons have become permanently and rigidly shortened, however, only the severing of the cords by the knife, can give any hope of a permanent cure. The operation should be performed by a skillful surgeon, and the animal cannot be put to hard work for several weeks afterwards. Although the operation is a simple one, its results are often far from satisfactory, and this fact must be considered before it is undertaken. There is always a tendency to contraction of the tendons again, in spite of the means employed to overcome this condition.

PARTURITION FEVER. MILK FEVER. PARTURIENT APOPLEXY.—Mr. W. L. Fulton, Pioneer, Ohio.—These names are given to a diseased condition, which may attack cows within twenty-four hours after calving, and almost invariably proves fatal. The disease most frequently shows itself in animals that are large milkers, and are inclined to a fullness of blood, and that have been well fed previous to calving. The symptoms may be, at first, great dullness, stupor, heat of head and horns, followed by delirium, or the delirium may be absent, and loss of power over the limbs, accompanied by paralysis of intestines and bladder, and inability to rise. Whatever may be the particular condition of the animal as shown by the symptoms, it is dependent upon the peculiar state of the system at the time of parturition. Cows, which show a tendency to plethora, must be kept upon a low diet for weeks before calving. The diet should be of a laxative nature. Great attention should be paid to cleanliness, and to proper ventilation of the

premises in which they are kept. Particular care should be taken, that they are not allowed to have access to luxuriant pasturage. The disease having declared itself, the first and most important step is to administer a full cathartic, which should consist of two pounds, at least, of Epsom salts. If insensibility has occurred, give this by means of the stomach pump, and after a few hours the action of the purgative may be assisted and hastened by fomentations of warm soap-suds every fifteen to twenty minutes. If there is delirium with heat of head and horns, apply cold water, or bits of ice to these parts. Rub the body and extremities constantly, and draw off the milk frequently. The strength must be kept up by the aid of stimulants. The following answers an excellent purpose: Aromatic Spirits of Ammonia, two ounces; Ground Gentian, one ounce; Ale, one pint, to be given every two hours. Coldness of surface and of extremities must be counteracted by suitable coverings. It is important to maintain the erect posture, if possible. The chances of recovery under any circumstances are small, but this fact should not prevent us from using every exertion to overcome this malady. If recovery occurs, the animal should be fattened for the butcher, and not allowed to have another calf, unless the cow is very valuable, in which case great attention should be paid to the means for prevention of the disease.

DIARRHOEA IN FOWLS.—W. J. Hess, Goldendale, Washington Territory.—It would be difficult to form a correct diagnosis of the cause of death in fowls, without knowing more of the symptoms which they presented. The enlarged and peculiar state of the liver found on the examination of one fowl, does not prove that others were similarly affected. The length of time, from one to four weeks, during which the birds were ailing, precludes the supposition of cholera. Diarrhoea in fowls may be due to a variety of causes, among which may be mentioned improper food, inclement weather, change of diet, etc., or it may be a symptom of contagious disease. Unless long continuous, it is not worth while to resort to remedies, except to very simple ones. A complete change of food may often effect a cure, such as giving soft-boiled rice, barley-meal, or barley. To these first two, may be added a little powdered chalk, or a few drops of laudanum. If this is not sufficient, give five grains each of chalk, rhubarb and pepper, to which may be added half a grain of opium in the food twice a day, or perhaps better still, in a pill. Sulphate of Quinine should be added to the drinking water. To whatever cause the disease may be due, the affected birds should be separated from the healthy. The house and yard should be thoroughly cleaned and disinfected, by washing walls, perches, floors, with water, to which is added about six drachms of Sulphuric Acid to the gallon, by means of a common broom or brush. If possible, the healthy birds should be removed to new quarters for a time.

DEATH OF YOUNG PIGS.—Mr. Geo. W. Osborne, Hamilton, Madison Co., N. Y., writes us that he has lost two more pigs, three months old, from some obscure cause. For the first month he fed them on ground feed, corn and oats. Since then has been using cotton-seed-meal in addition, gradually increasing the quantity, until he reached the proportion of two of feed, to one of the meal. The pigs ate about twelve quarts of the clear feed daily, but only half of that amount of the mixture. The pigs were well housed and littered. Have had no clear water to drink, and very little salt. The post-mortem examination showed considerable inflammation of the digestive organs.—It is fair to presume from the appearance presented at the examination, that the cotton-seed was the cause of death, being an inappropriate article of diet for young swine, on account of its extreme richness in albuminoids. If given at all to young animals, it should be in very small quantities, and its effects upon the system carefully watched. We know of one case at least, where death of a pig was produced by an excess of this food. Clean water is essential to the well-being of swine, as it is to other animals, and experiments have abundantly shown the value of salt, not only for the general health of the pig, but also as contributing to the fattening process.

WEAKNESS IN HORSES.—A subscriber from Oil City, Verango Co., Pa., writes us that he has a horse eight years old, which appears to be weak in the hind-quarters, sweats easily when worked, and staggers about.—The animal is suffering from general nervous debility, exhibited most especially in the hind-quarters, and due most probably to previous sickness, from which he has never entirely recovered. Whatever the cause the treatment must consist of giving the best food and plenty of it, oats being preferable to corn. Great attention should be paid to keeping the skin in the most healthy condition, by proper grooming and plenty of friction. Good quarters and good ventilation are essential, also a moderate amount of work, with no excess. Give half an ounce of Powdered Gentian in his food twice a day. Treat the animal patient just as you would a person who is weak, and not yet recovered from some previous illness.

Productive Idaho Valleys.—The valley world around Caldwell is one of the western wonders. Boise Valley stretches out in the purest atmosphere, a distance of eighty miles of the richest available soil, interlaid with springs, rivers, and geyser wonders as well.

Fayette Valley, a semi-Swiss scene, takes in one hundred miles of the best meadow lands of the Territory. The Malheur Valley, seventy miles in length, holds in its precious soil and area, all possibilities to the farmer and fruit-grower.

Boise and Fayette Valleys are bordered and interspersed with timber lands, that would put Michigan forests to shame. Everything that can be produced from the soil in Colorado or the Sacramento Valley, can be raised in these valleys of Idaho, without irrigation.

Oregon Climate.—For years the "Oregon mist," has been a standing slur with the surrounding States and Territories, and to describe that "mist," would be to say, it is simply a heavy fog, without the chill and malarious taint, that sneaks along with fog in other localities. It never rains in torrents and showers in Oregon, but settles into a heavy dampness, without the least atmospheric disturbance; thunder storms are rare, hail storms, cyclones, hurricanes and blizzards are unknown to the State. After September the soil is kept moist in its dew bath; from the first of November, until the second week in May, the rainfall is regular and copious, insuring the best of crops, and the farmer's prosperity. The climatic conditions of this far-western State, are particularly adapted to good stock. The "chinch-grass," as it is known on the Pacific Coast, is the most healthful grazing to be found in the world. The draught horses of Oregon are remarkable for size, health and endurance. The winters cannot be called severe, when, west of the Cascade Range, the farmers allow their stock to roam the year through, without any attempt at housing or feeding. L. LESTER.

The Herbage of a Permanent Meadow.—The great value of the experiments conducted at Rothamsted, Eng., by Messrs. Lawes and Gilbert, has often been acknowledged in these columns. One important feature of these experiments is their continued character. Results derived from the same treatment of plots of ground for twenty and thirty or more years, have a value far beyond those experiments lasting but a year or two. In the report now before us, we have only one class of results from twenty years' experiments upon a meadow of mixed herbage. The "Agricultural Results" were published in 1880. The present report gives the "Botanical Results," and is the work of that most conscientious and pains-taking botanist, Dr. Maxwell T. Masters, editor of "Gardener's Chronicle," London (Eng.) This report occupies over two hundred and thirty of the ample quarto pages of the Transactions of the Royal Society, and is illustrated by tables that are wonderful in their completeness. The object of these experiments, which have been continuous for over twenty years, was to show the effects of fertilizers upon the herbage of a meadow. Some twenty-two plots were carefully measured, some were left without any treatment, and others had weighed quantities of manure and different fertilizers applied to them. Records of the fertilizers, and their effect upon vegetation, have been made from year to year. These experiments involved a vast amount of mechanical labor. To take a fair sample of the herbage of each plot was no small task. The collectors followed the mowers, and a portion was taken from each swath; these portions were carefully mixed, and a sample of ten or twenty pounds taken for examination. The specimens from each plot were overhauled and assorted by experts, including boys, who became wonderfully skillful in detecting the different plants. An account was made of the numbers of each species, and they were also grouped as graminaceous (grass-like) plants, leguminous (clover and related) plants, and miscellaneous, mainly weed-like plants. These results are presented in tables, allowing a comparison to be made of the effects of different fertilizers. Should a study of these show anything of value to our farmers, we shall make use of them. Our present object is to acknowledge the receipt of this remarkable contribution to scientific agriculture, and again to call the attention of our readers to the extensive, accurate, and most valuable experimental work carried on at Rothamsted, England.

Burning Out Stumps.—E. L. Burnett, Nunda, Colo., asks our opinion of the following method of destroying stumps: "In autumn or winter bore a one or two-inch hole eight inches deep. Drop into it one or two ounces of saltpetre, fill the hole with water, and plug it up. In spring remove the plug, pour in a gill of kerosene and ignite it. The stump will smoulder away without blazing, to the extremity of the roots, leaving nothing but ashes."—The above "recipe" has been going the rounds for several years. That saltpetre will cause a green stump to disappear in this manner, looks as improbable as that a stump holding a gill of kerosene will "smoulder away without blazing." Still, we have not tried it. If any of our readers have, will they kindly give the result?

An Inexpensive Pudding.—When eggs are as scarce and costly as they often are, we can commend the following, if as good as that we have tasted, made by this recipe: Have ready a pint of bread crumbs, a quart of sour apples, pared, cored and chopped moderately fine; a full cup of sugar, and two or three tablespoonfuls of butter. Bitter a pudding dish, begin with a layer of apples, sprinkle over them some sugar and a few bits of the butter, nutmeg or cinnamon as desired, and cover with bread crumbs; then more apples, etc., repeating the layers until the dish is full, the top being bread crumbs. Cover tightly and steam three-quarters of an hour, finally browning slightly in the oven. To be eaten warm, with cream or butter and sugar rubbed together.

Household Recipes.—Without a variety of available fresh fruits for the preparation of desserts, the following recipes will supply the deficiency most admirably: *Suet Pudding.*—One cup each of beef suet, chopped fine, raisins chopped, sweet milk, sugar, three eggs, four cups flour, a teaspoonful soda, two of cream tartar or four even teaspoonfuls baking powder, and a little salt. Steam two hours. Half of above is sufficient for five or six persons. For sauce, use cornstarch or sweet gloss starch, made the same as for thick laundry starch. Season well with butter, salt, sugar, and extract of lemon.—*Orange Shortcake.*—Two eggs, one cup sugar, beat quickly and lightly together, add five teaspoonfuls cold water, one cup flour rounding with two teaspoonfuls of baking powder, sifted together, a pinch of salt, flavor with lemon extract. Bake in two jelly pans in a hot oven. For icing use one cup sugar, two tablespoonfuls water, and boil until it threads from the spoon. Remove from stove, and when a little cool stir in the white of one egg, well beaten. Slice three or four oranges, spread the cake with the icing and a layer of the slices; then add the second layer, treating the top in the same manner. Serve cold with sweet milk or better still, whipped cream. HAZELWOOD.

Gas-Lime as a Fertilizer.—With the continued extension of gas-works, even to quite small villages, there is an increasing amount of so-called "gas-lime;" and, taking the year together, no other single question comes to us so often, as, what is the value of this product as a fertilizer? When fresh from the gas-house it has an offensive odor, and so many associate unpleasant smells with fertilizers, that they frequently overestimate this material. When illuminating gas is produced by heating bituminous coal in the retorts, several impurities are mixed with it, sulphur or compounds of sulphur among them. To remove these, one part of the process is to pass the gas, on its way to the distributing reservoir, through boxes of fresh-burned lime. The sulphur unites with the lime, and forms calcium sulphide, formerly called sulphide of calcium, or sulphuret of lime, etc. When the lime ceases to longer act efficiently, it is thrown out, and fresh lime introduced. This refuse lime is constantly offered to farmers as a fertilizer, often at a nominal price. Properly used it may be as valuable as a mixture of common lime with some land plaster; improperly used it is poisonous to plants, as many have found to their cost and disgust, and when the sulphur and lime, or the calcium sulphide, is exposed to the air for a sufficient time, the sulphur is oxidized to sulphuric or sulphurous acid, the calcium (or basic metal of lime) is oxidized at the same time into lime, and the union of the two forms sulphate or sulphite of lime, or both. The sulphate of lime is the same as plaster, gypsum or land plaster, so much used as a fertilizer. The rest of the refuse is mainly common slaked lime, though usually carbonated, making it just the same as air-slaked lime that has been sometime exposed to the atmosphere. It will thus be seen that while the fresh gas-house lime is not a safe application direct to crops, or to soils to be soon seeded, yet if it be left sufficiently spread out, (better under cover from rains, but not absolutely essential), until disagreeable odors have mainly passed away, which may take place in from two to six months, or longer, the material is probably about equal to common air-slaked lime; or it may be somewhat more valuable on soils where land plaster produces good results,

Chat with Readers.

Lima Beans.—B. Miles, Lorain Co., Ohio, sends us a seasonable hint. He makes the hills for the beans four feet apart each way, in two rows. After setting the poles, those of four hills are brought together at the top, and firmly tied with tarred twine. These poles soon become covered with vines, and stand so firmly, that he has had none blow over, while the beans hung down in the leafy tents thus formed, in such a manner that Mr. M. says, "it is just fun to pick them."

Making Straw into Manure.—Mr. J. J. Ballinger, Cheney, W. T., asks us for a good way to convert straw into manure. We know that live stock will do this most satisfactorily.—Feed the straw to sheep or cattle, with a daily ration of grain or hay, or both. If the straw must be reduced to a field fertilizer without the aid of the animal system, it needs to be kept continuously moist. If this is not possible, the straw may be plowed under, where it will afterward decay. If none of these methods are available, the straw may be burned, and the ashes applied to the land.

Trouble With a Rose Bush.—Mr. C. L. Whitman, Ludlow, Ill., sends us a young rose bush, with an excrescence, the size of an English walnut, growing upon the stem, just below the surface of the ground. The swelling has all the characters of a gall, and is no doubt due, like other galls, to insects, which pass their larval state in them. We were unable to find the insect, though as the frontier men say, there was "a plenty of sign." It is a proper precaution to burn all such excrescences that may be met with, whether they occur above ground, or below the surface.

A Stimulant for Tomatoes.—"Beginner," Wakefield, Mass., asks, "What artificial fertilizer can be used upon a crop of tomatoes, to give a quick and temporary result?" The soil for tomatoes may be easily made too rich, and the vines stimulated to rampant growing, rather than to fruit bearing. A light, sandy soil, with a little well decomposed stable manure in the hill at planting, gives better crops than a strong soil heavily manured. Of the artificial fertilizers, a good superphosphate is likely to give the best results. A tablespoonful or so to each plant, to be worked into the soil at the time of setting out, or rather more applied later, when hoeing, will probably be of good service.

Cabbage Maggots.—Mr. O. D. Smith, Andes, N. Y., writes us, he has been troubled for the past few years with a small white maggot on the roots of his cabbages, both while in the seed-bed, and after they were set out. They eat off all the small roots, and sometimes bore the stem. The maggots are apparently those of the cabbage-fly of Europe (*Anthomya brassicae*). When a third of an inch long, they leave the infested cabbage and pass into the ground, from which, after pupation, the mature flies come forth. Several broods are annually produced. The best remedy thus far employed is lime, which is best applied in the form of lime-water. Superphosphate as a fertilizer acts as a preventive. It is not best to grow successive crops of cabbage on the same soil.

Catching a Wild Cow.—Mr. F. W. Godsal, Fort Macleod, Alberta, Canada, wishes to know if there is any plan or trap for catching a wild cow by the head, and holding her in order to milk, or otherwise handle her.—Have a set of stanchions set in some shed, or even an open yard, into which the cow may be driven. Then if feed is placed in front of the stanchions, she will be forced by hunger to put her head through, and then by pulling a cord the movable stanchion may be shut, and the cow caught. You will have a good time "gentling" her, but be patient and do not strike her, or hurt her in any way. One blow or kick will undo all the progress towards taming her you can make in half a day. Tie her legs to milk her, but do not hurt her.

Grape Rot.—Mr. J. H. Glem, Coulterville, Tenn., writes us, that he has been much troubled with grape rot. We do not know of any certain remedy for this disease of the vineyard. This destructive work is doubtless that of a small, parasitic fungus. The fungus plant preys upon the juices of the berries, and causes them to change color, and finally drop off. Some grape growers have used Flowers of Sulphur with some success. This substance, when applied to the foliage, has proved a remedy for the leaf mildew, so prevalent in many parts of the country. The rot of the berry is much more difficult to reach. Paper bags placed over the clusters just after flowering, tend to keep off all disease germs, and have served well in other respects when employed.

The Quince Borer.—Mr. J. A. Price, Mt. Vernon, N. Y., writes us for a remedy for the quince borer. This pest of the orchard was described, with engravings, in the December *American Agriculturist*, 1883. The striped parent beetle deposits its eggs in the bark near the base of the tree, from June to August. Petroleum paper wrapped around the tree, partly below ground, will keep off the beetle. The deposited eggs are killed by an alkaline (potash or soda) wash. Two pounds of whale-oil soap, and four ounces of sulphur, in a pailful of water, is a cheap and reliable mixture to apply to the trees. The borers already at work should be cut out, or killed in their burrows with a wire probe. A knife in careless hands may do even more damage than the borers. Cut away only enough bark to admit of reaching the intruder.

Pig Raising.—Mr. L. M. Stearns, Cardiff, N. Y., wishes answers to the following questions: What is the most profitable kind of swine that have the following qualities—easiest keepers; fatten at any age; do well on red clover; make

from one hundred and fifty, to two hundred pounds of pork at eight months old, and will do to raise in Central New York?—The small Yorkshires (white), and the Essex (black) are the easiest keepers. They will fatten at any age, in fact, if they are fairly well fed, are always fat. These pigs do well on red clover, keep fat, and will make two hundred pound pigs at eight months old. A cross-bred pig will do better. Say pigs half small Yorkshires, and half Berkshire, with the latter for their dam, or the Yorkshire or Essex crossed upon big sows of any breed. You can raise any kind of pigs you wish in Central New York, if you will take care of them, and if not, you had better not raise any.

Preparing Fish as a Fertilizer.—"Amateur," Artondale, Wash. Ter., can get any quantity of fish, but is at a loss how to use them. He procured six tons last fall, and stratified them with alternate layers of earth. This spring they are not half decayed, "while the perfume is horrible." On the Atlantic Coast, the fish guano is a secondary, or at least a joint product. The fish are first pressed for their oil, the meat and bones are then dried and ground, and in that condition the fish scrap decomposes very readily, either in a compost, or applied directly to the soil. The oil is of no value as a fertilizer, and retards the decomposition. Still you have had your "fish pie," made only during the cool months. We do not know what kind of fish you used, but it can hardly be more oily than the menhaden, which the New England and Long Island shore farmers formerly composted in the manner you described. Warm weather will no doubt hasten the process, and the odor can be suppressed by a thicker covering of earth upon the heap.

The Transmutation of Grain.—"A. W. M.," Alamosa, Col., asks us if it is a fact, that either in England or America, oats have been sown, and after the crop had been fed off by sheep the first season, the second year a crop of barley has been reaped, no other seed having been put in in the mean time. Also, has wheat in like manner resulted from the sowing of barley? That both barley and wheat may have appeared under the above conditions is possible, but that oats ever change into barley, or barley into wheat, we have no proof. These belong with the still more general belief that wheat will produce chess. Numerous people are ready to assert that they have seen these transmutations, but when asked to show them to others, the evidence always fails. Elihu Burritt, known as the "Learned Blacksmith," recorded his observations in England in a book, in which he gravely stated that he saw a case of the transmutation of a field of one kind of grain into another. The farmer declared he had sown wheat, and there was a field of barley, or *vice versa*, and the wonderful fact was written down, and appeared at length in a costly book. Mr. Burritt was probably "learned" in many things, but not in what constitutes evidence. We have been on the look out for a stalk that was partly wheat and partly chess, for these many years, and have failed to see one.

Salt as a Fertilizer in the Orchard.—A. W. Langdon, Erie Co., N. Y., asks our advice "as to the quantity of salt advisable to use about fruit trees in an old orchard." There is no more positive knowledge as to the value of salt as a fertilizer for fruit trees, than there is regarding its utility when applied to field crops. The fruit trees to which it appears to have been most beneficial, are the plum and quince, and on these it has been used more as a remedy for diseases, than as a fertilizer in the proper sense of the term. Salt in sufficient quantity applied to the roots, will destroy all vegetation, including the largest trees, hence caution must be exercised. Mr. Meech, the successful quince grower of New Jersey, advises a pint to be applied to the soil around quince trees that are two or three years old. Whether salt will produce a better effect upon old orchard trees than a good dressing of fine bone, we much doubt. If applied to old orchard trees, we should prefer to try two quarts, sprinkled upon the soil as far as the roots extend, to a larger quantity. We hope Mr. L. will try the salt, and also upon some of the other trees, a liberal dressing of ashes, of bone flour, and stable manure, and report the comparative results.

City People as Farmers.—J. Reese, Covington, Keaton Co., Ky., asks: "Can city people make a success of farming?" That depends—if the people are in successful and profitable business in a city, they may possibly make enough to allow them to live on a farm. This is a frequent question, and the answer is not intended to be a trivial one. The question gives expression to a too common opinion, that a farm will somehow run itself, and not only afford city people a rural home, but it may return an income besides. A farm, to be successful, requires all the care and business application that is needed in any other business. If one who has built up a profitable business in dry-goods, hardware, or groceries, in a city, upon moving to a farm will apply to farming the same business methods that have made his city occupation profitable, the probabilities are that he will succeed at farming. Unless he does this, and if he at the same time continues his city methods of living, a failure is certain to follow. We would not imply that farmers should live any more poorly than city people. A merchant or tradesman works for money and with that, everything consumed in the family is purchased. On the farm, the object is to produce everything, so far as may be, that is consumed by the family. A different kind of economy must be studied. The provisions needed by the family must be largely produced on the farm, and for the few things that must be brought to the farm from the outside—coffee, sugar, clothing, and a few others, something must be produced that will sell readily and bring the money, to allow them to be purchased. City people who turn farmers may succeed if they will really become farmers.—If they remain city people, they had better remain in the city.

Farming in England.

ALFRED TRUMBLE.

During a recent tour of Europe, the writer spent most of his time among the farmers of the countries he visited. He was familiar with country life at home, and everywhere contrasted the condition of the foreign farmer with that of the agriculturist in the United States. It is for the purpose of il-

AN AGRICULTURAL LABORER.

lustrating these contrasts, that he presents this sketch and its accompanying pictures to the public. Everything about farm-life in England is strange to American eyes. The great waste of land and labor in hedging and ditching is striking to one accustomed to our own more economical and ready system of fencing. All year round, the care of hedges and ditches on a farm of any size, keeps

THE PLOW-BOY.

several men employed, and the farms themselves seem strangely cramped to one accustomed to the broad, open stretches of the West. The people in their odd dress, work more slowly than do the

laborers in our own fields; the horses are larger, heavier, and more deliberate in their movements, and the implements of farming are often unwieldy and ridiculously primitive in form. Almost the only feature of the country in England that strikes an American as enviable, is the magnificent roads, which even in the worst of weather, are fairly good for travel. The spirit of improvement is now spurring the English farmers into an approach to the enterprise of our own land. Agricultural schools are doing good work, and modern machinery is being extensively introduced. In Suffolk, Norfolk, Lincoln, and some other counties, agriculture has attained to a high degree of perfection, but in others it is in a primitive state.

Land in England is more frequently leased than owned by the farmer. Many leaseholds have been in one family for generations, and their holders could buy the land as far as money was concerned, but the great land-owners will not sell it, and the farmer remains a tenant. He may pick up odd spots of ground here and there, and often will be found farming lands of his own ten miles apart, and residing and cultivating a large estate, for which he pays rent as well. Wheat, barley, and stock-farming, are the great agricultural interests of England. In the western counties, where the climate is more suitable for grass and less so for wheat, dairy farming and stock-raising rule. The eastern counties furnish the wheat-land, but all over England are found permanent pastures, where countless herds fatten. Yet the supply of meat is still so insufficient, that large imports from America are necessary.

America is, indeed, the great bugbear of the English farmer. As a recent statistician truly observes: American competition has reduced his profits on grain-growing and beef-raising more than fifty per cent. He pays a higher rent than we do, and uses more expensive machinery. Moreover, the high rent forces him to demand high rates

for his productions. American wheat and American beef can be landed at Liverpool at from a quarter to a third less the bushel and pound than the English can be sold for, and still pay our own farmers a better profit. The English farmers are like their tools—built to last, but not to work fast. They take things easy, and are little interested in affairs off their farms. They do not read many papers, and almost their only relaxation is found at an annual fair or two, and at election time. Of late years, the sporting farmer has formed an exception to the rule. He imitates the follies and extravagances of the great folks, goes hunting, plays billiards, bets on the races, and drinks his way down the road to ruin, rapidly and easily, but he is an exception fortunately, and will remain one.

The English farmer is a good feeder. He believes in treating himself and his household well. His house is commonly as solid and old-fashioned as his tools. One Welsh farm-house, of which we present a picture, is more than four hundred years old. Its tenant is a very wealthy man, but he cannot buy it, though he desires to do so and rebuild.

Here and there are found old manors, deserted to the winds sometimes, at others still inhabited. They are absolutely sepulchral in their gloom, and justify the ghost stories with which they are one and all associated. The mansions of the great land-owners, ancient and modern, are, on the contrary, marvels of luxury. In them science has remedied the imperfections of the past. The proprietors of some of these estates farm them them-

selves, on a vast scale, frequently with American methods and machinery.

Society in rural England is divided into as rigid departments as it is in the cities. The squire steps aside to let my-lord pass, and the tenant-farmer takes off his hat to the squire. As for the agricultural laborer, he doffs his hat to every one, from the great man of the district down to the "squire's man," whose business it is to keep his master posted on all the small goings-on of the community he lords it over. The English agricultural laborer is a singular individual. Except that he has a permanent home, he is no better than the tramp hands who are employed upon our great western farms, when the season comes round. He is absolutely uneducated, and he knows little more of the soil he helps to cultivate, than the horses which drag the plow or the crows which follow the sower. He begins life as a crow-boy, sitting on a fence and shouting all day long, to keep the crows from plundering the furrows; he ends life a man of full size, but only a child in intelligence still.

THE SPORTING FARMER.

THE SQUIRE'S MAN.

The condition of the English agricultural laborer varies with that of the district to which he belongs. On poor lands, he earns at the best eight shillings (about two dollars) a week, on good ones he rises to fifteen and even twenty. In some districts, we find him living rent free, in others he has to pay rent. But whether he pays the rent in money or not, the landlord gets its price from him, and to keep body and soul together, he must work constantly and put all of his family at tasks. His sons begin to do some kind of service almost as soon as they can walk. Then they are promoted to the plow, or otherwise to assist about the farm. If such a boy can get a job in the barns or stables, his highest ambition is achieved.

The misery of the bulk of agricultural laborers in over-crowded England is indescribable. Numbers have of recent years been sent to Canada and Australia by popular subscription, but the mass which remains is in no better condition than before. Not a little of this is due to himself. Many landlords do their best to improve the condition of their laborers, but those who should benefit by their efforts, are so steeped in ignorance and so unmannered by hardship, that they are incapable of assisting their benefactors in their good work.

An English writer not long ago said: "Though slavery has been unknown in England for centuries, we have, in the agricultural laborer, a creature who is a slave in everything but name. He is a vassal of the soil. He belongs to the same estate his great grandfather did, just as a Russian serf be-

PAST AND PRESENT OF ENGLISH FARM LIFE.

Drawn and Engraved for the American Agriculturist.

longed with the land he tilled. Only, where the serf was tied down by law, he is chained by poverty, ignorance, and degradation."

Our agriculturists are progressive, intelligent,

unwearying in their efforts for advancement and improvement. In 1862, Horace Greeley predicted exactly what has come to pass. With improved machinery and advanced ideas, the American

farmer can more than compete with his English cousin, thousands of miles away. The American farmer has himself to work for, and he knows the land he improves will benefit his children.

A Small Barn.

E. O. LEE.

A general barn should provide ample store-room for hay, grain, straw, etc.; comfortable quarters for the live stock; convenient storage for wagons and all farm implements, and the best arrangements for making and preserving fertilizers to be returned to the land. The plan herewith present-

Bins for other grain may be constructed on the other sides as desired. The loft over the granary is reached by a step-ladder (the fruit-ladder may be kept there), and is a good place to store lumber, fruit packages, etc. The horse stable, fifteen-and-a-half by sixteen feet, is divided into three stalls and has no floor. The slide door opening into the side shed is used in getting in dry earth and other absorbents, while the manure is thrown out at the rear door. A small door next to

Fig. 1.—EXTERIOR OF A SMALL BARN.

ed (figs. 1, 2, and 3), is for a barn thirty-six by forty feet, with a lean-to shed upon one end. The threshing floor (fig. 2), eleven feet wide, is entered by a sliding door ten feet high, kept in place at the bottom by a hewed sill, placed nearly on the level of the floor and even with the gravel drive-way outside, making an easy entrance for heavy loads. First, at the right, entered by a door-way three feet wide, is the shop six by six feet, provided with work-bench, vise, etc., and lighted by two small windows. There is also a window of six, nine by fifteen, lights above the entrance, and a similar one at the other end of the threshing floor above the roof of the shed, which admit of all the light needed. Next to the shop is a floorless room eleven-and-a-half by sixteen, suitable for a wagon and farm tools, and is entered by a sliding outside

the stairs is very convenient, and a similar one opening into the rear stall makes a good place to feed a calf when one is kept there. The hay bay has a girt in front two or three feet high, supported by short studs, upon which boarding is fitted tight to the floor, to prevent any escape of grain in that direction while threshing. Similar boarding in front of the cow stable will serve the same purpose and keep the fodder in place. There should be a permanent ladder at the side of the centre post, reaching from the bay girt to the beam. The boarding in front of the stall next to the bay-mow should be binged, so as to allow a passage-way there when the stall is not occupied. A sliding door at the rear affords a convenient place to supply absorbents as well as a short passage to the shed. Through a sliding-board window, eighteen

by eighteen inches, the manure may be thrown into a shed, where it can be worked over by hogs when desirable. The mangers should be two-and-a-half feet wide, and provided with comfortable ties. The rear door of the threshing floor need not be more than eight feet wide and seven-and-a-half feet high, to slide on rollers like the others. The stable doors opening into the yard might as well have hinges. The cistern, seven or eight feet in diameter, should be properly protected from the yard and supplied with a pump and trough. A gate between it and the corner of the barn would allow the passage of a wagon when desired. There may be a floor over the rear part of the threshing-floor on a level with one in the shed, thus making more room for straw or fodder. The following estimate contemplates boarding the outside with ordinary barn boards, and lining the cracks with cheap half-inch stuff two to four inches wide, except the gables, which are without lining and

corn could be shovelled from the wagon and afterwards into the crib. A chute might be constructed, through which grain could be taken directly from the bins to the bags on the wagon in the shed below. The broad boarding upon the side of the wagon-room and granary affords a good place to hang rakes, hoes, shovels, forks, etc., where each can be taken down without disturbing the others, and all be convenient and out of the way. The general appearance of the building might be improved by using dressed boards of uniform width, and covering the cracks with good battens; and further by surmounting the roof with a neat ventilator, and covering with paint. The stables might be paved and cemented at no very great cost.

Practical Poultry Suggestions.

There need be no trouble in moving sitting hens from the nest in which they have been accustomed to lay, to the one prepared for sitting. The nest should be made before the hen is disturbed, and so arranged that she can be shut in for a day after being moved. Place the eggs in the nest and after dark set the hen gently on them, and leave her as soon as possible. Fowls accustomed to handling will not object to this change. It is well if possible to set them in a place away from other fowls, where they will be perfectly quiet and in partial darkness. Give the fowls intended for breeders a free range until planting time at least. This will keep them in a thrifty healthy condition, and prevent an accumulation of fat. A large percentage of eggs will hatch, and the chickens will be stronger and get a better start.

Small coops for chickens should have a bottom, otherwise the digging of the hen in the ground will make hollows in which water may collect, and if the chicks are not drowned they will get wet, which may lead to cold and roup. To make a continuous growth, chicks should be dry and warm at all times. A comfortable coop is shown in the engraving. If one wishes to be very careful of a few

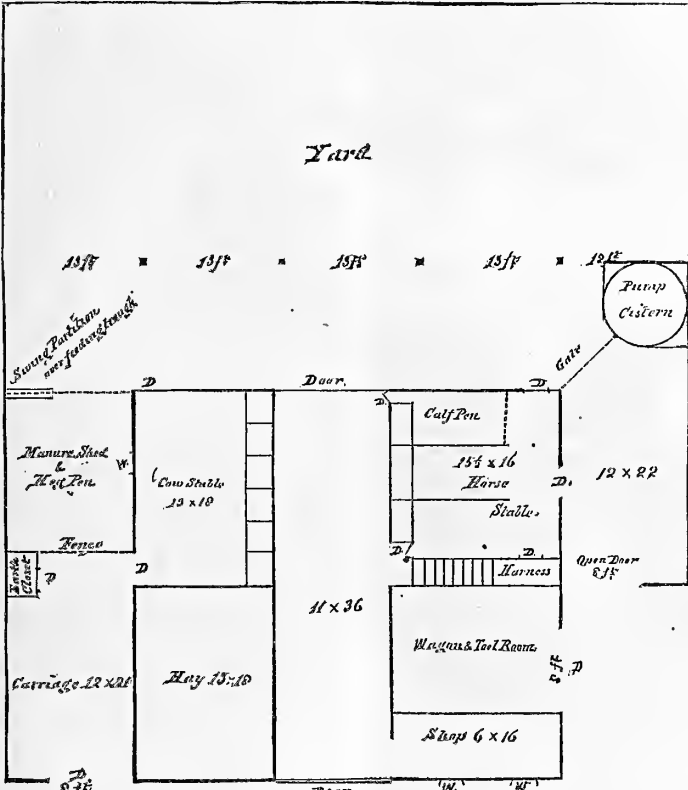

Fig. 2.—MAIN FLOOR OF BARN.

door eight feet wide. A stairway, starting two feet back from the line of the threshing floor leads through a passage two-and-a-half feet wide, to the floor of the scaffold and granary. The latter (fig. 3), sixteen by eighteen feet, entered by a door three feet wide, is provided with cribs for corn on two sides, two-and-a-half feet wide and nine feet high, sufficient for four to five hundred bushels of corn.

lap over the boarding below the end rafters, being set flush with the same. The crib sides of the granary should be boarded with strips three or four inches wide and an ineb apart, being set upon a narrow piece of zinc, nailed over the ends of the lower boards to keep the water out.

In the side of the granary, between the bins and crib, there might be an opening, through which

choice chicks, small wooden wheels can be placed on the side near the rear end, so that the coop and contents can be trundled under a shed, or on to the barn floor until a shower is over. Young chicks should be fed in small quantities, and as often as once in three hours. Give only what they will eat clean at each feeding. A mixture of corn-meal, and ground oats is very nourishing, and should be either wet with boiling water, or baked in a cake and then soaked in warm milk. Feed no hard grain until six weeks old, and up to this time chicks

A MOVABLE CHICKEN COOP.

need no drink, though they will enjoy sour milk occasionally. The most critical time in the growth of chickens, is when the stiff wing feathers begin to grow. After this period is passed, they will push along rapidly, and should be ready to dress as broilers in ten to twelve weeks, when at from thirty-five to forty cents a pound, they will bring as much as if fed until six months old, and sold at fifteen to twenty cents. Save large, finely colored eggs for hatching; it pays well to choose the best product of the hens for improvement of future stock, as in saving seeds from the best vegetables and flowers. If the best layers, and the layers of best eggs are chosen from year to year, the poultry stock will greatly improve. This rule applies as well to the fancier who wishes to improve the appearance of his fowls by breeding for marking and symmetry, as to the farmer and producer who keep a few fowls for home consumption only. H. C. B.

Pasture and Meadow Grasses.

COL. F. D. CURTIS.

A variety of grasses is best for pastures, so that there may be a continuous growth. The seeds of grasses, as well as other seeds, when buried at such depth that they do not germinate, remain dormant for a long time, and will grow when brought by tillage near the surface. There is always more or less self-seeding, as the earth is filled with seeds which have accumulated and only waiting favorable conditions to show themselves. It is not always necessary to sow a variety of grass in order to have such a sort represented in a pasture, but of course a variety is more certainly secured by so doing. If the soil is made rich before seeding, it will help to increase the yield of self-seeded grasses. Making the surface smooth and fine will also aid in bringing out the latent seeds.

For a pasture, variety of grasses should be selected adapted to the land and the purpose of the pasture. Timothy (*Phleum pratense*), is the poorest of the cultivated varieties of pasture grasses, as it makes very little leaf herbage, and after the stems have matured the after growth or after-math is small. It is the best grass for meadows of any single variety, both for yield and market, being better suited to horses than cattle. It is among the poorest for sheep. The best single grass for pasture is orchard grass (*Dactylis glomerata*). This is also the earliest, except the small blue grass (*Poa pratensis*), so common in old pastures, dooryards, and along the highways. Orchard grass is valuable for its prompt renewal after either cutting or grazing, and for its permanency, being superior to Timothy in this respect, and not excelled by any, unless it is Red-Top (*Agrostis vulgaris*), on rich land it will furnish a fresh bite in three days. No other grass is equal to it in this respect. It should always be allowed to produce an after-math before cold weather sets in, or the crowns will freeze and die. The after-math acts as a protection and is necessary in a cold climate. It will not, however, cut

so readily as either Timothy or clover, owing to the form and tenacity of the roots, which are long and fibrous, and grow in bunches. The sod makes more enriching material than any other grass. An orchard grass sod always makes mellow land, as the roots penetrate to a great depth and loosen up the sub-soil. The roots of Timothy are small and of shallow growth, hence are easily thrown out by frost and make a weak sod. Orchard grass is not so well adapted for meadows as other varieties. It ripens at an inconvenient time, before the spring work is finished, and does not produce so large a crop or as good a quality. Unless cut when in blossom it is hard and woody. Timothy is much better if cut when the seed is beginning to form. Timothy will flourish either on dry upland, or low land if it does not heave with the frost, so as to throw out the bulbs. Orchard grass is also adapted to any variety of soils, except very wet land. Red-Top grows well on moist land, even if it overflows, and it will also do well on dry land. It makes hay of excellent quality, good for any kind of stock, being softer in its texture than either Timothy or orchard grass, and lighter in proportion to the hulk. It is next, if not equal, to orchard grass in value for pasture, with the exception of extreme earliness and quick renewal after cropping.

Silk Culture—Food Plants.

MRS. M. J. G. HAMMACK.

There are hundreds of thousands of women who, being unable to do hard work, have no means of converting labor into capital, and to these silk culture is really the creation of a new industry. For the infirm, the invalid, and the child, it is the open door to a competency, with no burden of drudgery. Let no one suppose that the cultivation of silk is a difficult pursuit, for it is a very simple one, and as instructive and interesting as profitable. There is no real obstacle to its success in America, for the dry and bracing atmosphere of this country is extremely healthy for the worms. One of the advantages of the silk industry is that a comparatively small amount of capital will yield a large income, so that to a person with limited means and a family of children, the culture of silk holds out encouragements of extraordinary promise. Women and children can make one hundred dollars the first year after planting the trees, and the second, from one hundred and fifty to three hundred dollars, with one acre of mulberry trees.

The gathering of the leaves and feeding the worms may be done by the children, one adult person always directing the business. It should be borne in mind that in silk culture the brain is of more importance than the hand. The first important step is to prepare the proper food for the silk worm. The leaf of the mulberry is the best, and this tree will grow and the silk worm thrive upon it throughout the United States. The maclura or osage orange, is a substitute for the mulberry, and a fair crop of silk can be raised from it, but any one hoping for complete success in its use may become discouraged. The danger in handling the thorny osage, the difficulty in securing sufficient leaves on account of the thorns, the danger of the succulent leaf at the last stage of the worm, and the great care to be observed in not using the upper end of the shoots, should prevent any one from relying entirely upon the osage as principal food. It will answer to experiment with while the mulberry trees are growing, but to use osage entirely, doubles the expense, both in gathering leaves and using the branches. Worms fed on branches are the most healthy, as that is their natural way of living, and they enjoy creeping about on the twigs. The mulberry will ever retain its superiority as a reliable and continuous food for the certainty of

yielding an unexceptionable quality of silk, and its vigorous growth and production of suitable foliage invest it with properties not combined in any other plant. One-year-old trees can be used to make a crop of silk, and where the plants are set out close together as for a hedge, the clipping of the twigs and branches will favor the growth of numerous shoots which will become valuable leaf-bearing branches the next season.

For standard trees they should be set out twelve feet apart each way, and in this mode of cultivation the trees interfere but little, if any, with the use of the land for other purposes. Corn and small fruits may be grown between the rows of trees. Planting in hedge rows is the most approved mode of cultivation for convenience in gathering the leaves.

The Moretti mulberry is profitably grown for a hedge, as the large size of its leaves make it a very desirable variety. The Italian mulberry is generally preferred to all other kinds. It grows rapidly, and is clothed with leaves fifteen or twenty days earlier than the other varieties. The Russian mulberry has taken a very prominent place, and owing to its hardness and rapid growth is in great demand; it produces fine, strong silk. The trees make excellent timber and are prolific fruit-bearers. The aromatic and juicy berries are often more than an inch long, one half inch in diameter, and vary in color, from jet black to light red. The fine fruit more than pays for the labor and expense of growing these trees. All the varieties of mulberry trees mentioned are hardy, grow rapidly, attain a height of twenty or thirty feet, and make beautiful shade trees.

A Pig-Pen in the Pasture.

The pig pasture should be near the house for convenience in feeding. But wherever located, it should have a good pen for feeding and shelter. A pen is an economical arrangement in the matter of feeding alone. When pigs are fed on the ground much of their food is trampled into the ground and wasted. Loose troughs placed in the open field are insecure, and the strongest hogs usually get more than their share if they do not succeed in overturning the whole mess. It is a bad policy to leave pigs exposed to all sorts of weather, even during the summer season. When animals seek the poor protection of a fence or a tree, one can easily understand that shelter is needed. Farm animals are good guides to follow in supplying their wants in this respect. A shelter should be provided that will exclude cold rains, frost, and the hot sun. This may be done at small expense. Two or three

A CHEAP PASTURE PIG-PEN.

hundred feet of lumber and a few hours' labor, will erect a pen that answers all the wants of the case. The accompanying cut represents such a pen situated on the line of the pasture fence, with feed spouts accessible from the outside of the pasture.

The frame for this pen is made by setting posts in the ground, and spiking sleepers, girts, and plates to them. These posts should be of some durable timber, cedar and tamarack are excellent for this purpose. Any timber may be made more durable by pouring hot tar over the portion that is to enter the ground. The posts should be set about three and a half feet in the ground. Where the boards are put on horizontally, no girts are needed. Plates or overlays spiked to the end posts, and extending the length of the building, are needed to hold the roof boards, which run up and down, and are battened with narrow strips.

Common lumber is used throughout, the best of the lot being selected for the roof boards. A door is provided at each end. The trough is located at the front of the building, and the spout empties into this at a convenient height from the ground. Nesting places are in the rear of the enclosure, and the whole has a tight floor upon which corn may be fed without waste. If it becomes necessary to change the pasture, this building can be easily taken down and removed. It is a good plan to have two small pastures for calves and pigs, provided with shelters of this description. The animals can then be changed without the tearing down and erecting of shelters. Calves need shelter fully as much as the pigs, and about the same plan will answer for both.

W. D. BOYNTON.

Budding Forest Trees.

A. S. FULLER.

The propagation of woody plants by the process known as budding, consists in taking from one tree or shrub, a bud and transferring it to another. The plant upon which the bud is placed is called the stock. The limits of this operation are not very well defined, but for all practical purposes I may say that it is limited to the members of the same genus, or closely allied plants; that is, oaks may be budded on oaks, chestnut on chestnut, and generally the nearer related the species, the more successful the operation. But like all other rules pertaining to the propagation of plants, there are exceptions, and occasionally we may find that the wood of two species belonging to the same genus, cannot be made to unite and form what is termed a union. There is always a preference in stocks belonging to the same genus, and the propagator seeks the best for his purpose. I may say, however, that as a rule, the weak and feeble growing should always be placed upon the strong growing, if rapid growth and long life is the object in view.

Budding is usually performed in summer, soon after the buds or a portion of them are fully developed on the young wood of the present season's growth. The stock into which the buds are to be inserted must be in a similar condition, although the stem or branch at the point of junction may be more than one year old, but in no case must the bark be so thick and rigid, that it cannot be readily separated from the wood beneath, because the bud is to be inserted under the bark of the stock, and unless this can be done, the operation will fail. We have to depend upon the assimilated or true sap to form a union between the bud and the stock, the

present season's growth. The upper and immature ones can, of course, be discarded, if it is necessary to commence budding before all are in fit condition to use. In fig. 1, *a*, we have a bud which is to be transferred to a stock; a knife is inserted about one inch below it and passed upward, and brought out about a half inch above, cutting out a piece of bark with a thick slice of wood of a form shown by the circular line in the figure. We now make a cut across the stock, cutting just through the bark, and another longitudinally downward, as shown in fig. 2, then insert the lower end of the bark containing the bud, under the bark of the stock at the point where the incisions meet, and press it down to its place. If the bark of the stock is firm, and does not part easily to admit the bud, the edges must be lifted so as to allow the bud to pass under it freely. If the piece of bark containing the bud does not pass completely under, then cut it off at the upper end even with the cross-cut in the stock, so that it will fit in smoothly. In fig. 3 a bud is shown, taken out after the upper end has been cut off, as directed, and on this is also shown a portion of a leaf-stalk, usually left attached for convenience in handling the bud, as well as to protect it from injury. After the bud is inserted, it is secured in place by a ligature, which may be of bass bark, a strip of thin cloth, woollen yarn, or any similar material that will hold the bud and bark in place, until a union is formed. The point of the bud and leaf-stalk attached should, of course, be left exposed. The stock into which a bud is inserted should not, as a rule, be over an inch in diameter or less than a half inch, although much larger and smaller are often used. After the bud has firmly united with the stock—which will usually be in two or three weeks—the ligature should be loosened or removed entirely. The bud is not expected to push into growth until the following season, at which time the stock above the bud should be cut away and the bud allowed to grow undisturbed. If sprouts appear on the stock they must be removed, in order that all the strength may go into the bud. The horizontal incision in the stock is sometimes made below or at the bottom of the perpendicular one, and the bud thrust under the bark, but upward, or the reverse of the more usual method, this permits the downward flow of the sap to reach the bud in a more direct course than when the cross-cut is made above it. It is not a convenient method, but is sometimes desirable when the flow of sap is rather sluggish late in the season.

When a bud is taken from the shoot in the usual way, there is a small slice of wood remaining under the eye, which, in budding some kinds of plants, it may be desirable to remove, although it is an almost universal practice in this country to allow this wood to remain, and doubtless in a majority of cases, it is best to do so; but there are instances where a more permanent union will be secured if it is removed. With kinds of trees like the magnolias, horse-chestnuts, and common sweet chestnut, that have a rather thick bark on the young shoots, better success will be attained by the removal of the

Fig. 4.—TAKING OFF THE BUD.

wood from the bud. When this is to be done, the shoots used must be in a condition to allow the bark to peel readily from the wood, without tearing or breaking the fibers. Hold the branch in the left hand, with the smaller end towards you; insert the knife-blade about one inch below the bud, cutting a little deeper than you would if the wood were to be left in, pass the knife under and above the bud, some three-quarters of an inch, but not out to the surface; withdraw the blade, and cut across through the bark only about half an inch above the bud, then with finger and thumb lift up the bark, at the same time press it gently forward, and you will remove the bark and bud (fig. 4) *a*, without injuring it, leaving the piece of wood *b* adhering to the branch. This is a much better and more scientific method of removing the wood than to pick it out with the point of a knife, or to remove with a goose-quill as sometimes recommended. This concave piece of bark, with the bud attached, will fit the convex surface of the stock very closely, and on large stocks, and with buds from large shoots, taking out the wood is often advisable.

Another style of budding called the annular, and represented in fig. 5 may be practised in summer on small shoots of the season's growth, or in spring, so soon as the bark will peel readily from stock and cion. It consists in taking a ring of bark with bud attached from one tree, and after a similar ring is removed from the stock, the former is fitted into its place. This ring of bark may be an inch wide and fitted to stocks from the size shown up to an inch or more in diameter. It is always best to have the ring of bark wide enough to admit of placing ligatures around the stock above and below the bud, in order to hold it in place. When performed in spring, it is best to use waxed strips of cloth, to cover the wound and exclude the air, but late in summer and with bark from shoots of the present season, strips of bark such as used for ordinary budding, will answer for ligatures. In this style of budding, the branch from which the ring of bark is taken, should be nearly the same size as that of the stock to which it is affixed. In performing these operations an implement called a budding-knife is required, and they are made of various sizes and patterns, and are usually to be obtained at almost any seed store. The imported budding knives have usually either a thin, blunt-pointed ivory, or bone handle, or a piece of bone inserted into a horn handle, this being used to lift the bark of the stock, to facilitate the inserting of the bud under it. Many gardeners and nurserymen still use these old forms of budding knives, but they are clumsy affairs, and not adapted for rapid work. Any pocket knife with the blade rounded, and made thin and smooth, will answer.

Fig. 5.—ANNULAR BUDDING.

Fig. 1.

Fig. 2.

Fig. 3.

same as we do on layers and cuttings to produce roots, for all the operations are analogous, only in budding, the alburnous matter forms a union with the same material in the stock, while in the layer and cutting, it is emitted in the form of roots.

The proper time for budding trees must, of course, vary with the latitude, season, and kind of trees to be propagated, as some come forward earlier than others, but, as a rule, it may be performed as early in the season as good plump buds can be found at the axils of the leaves in shoots of the

TOBACCO STEMS FOR CURRANT WORMS.—Mr. A. P. Kinney, Jamaica Plains, Mass., writes us as follows: "In 1881 I came to this place, and found twenty-eight large currant bushes, that were in a very bad condition on account of the currant worms. The neighbors said that for eight years the fruit amounted to nothing, the leaves being destroyed every year. In the spring of 1882, tobacco stems were applied as a mulch, at the rate of ten pounds to each bush, and a handful scattered through the branches. The foliage was not troubled by the worms. In 1883 only five pounds of tobacco stems were used per bush, and the leaves were not destroyed. This year I shall use only half the last amount, and believe it will be sufficient."—Any currant grower who can readily get tobacco stems, should try this remedy for currant worms.

The Southern or Deciduous Cypress.

Few of those who read of the great beauty and remarkable aspects of the cypress swamps of the Southern States, are aware that the cypress tree will

Fig. 1.—CYPRESS BRANCH AND CONE.

flourish on dry land, and that it is hardy in localities far north of those in which it grows spontaneously. The lower portions of Delaware and Maryland are its northern limits in the wild state, but it is hardy throughout the Northern States, save in localities with exceptionally severe winters. There is a fine group of these trees growing upon the edge of a marsh, within a few miles of New York City, and the writer has a tree about the same distance from the city in another direction, which, upon the sandiest of soils is a fine specimen of vigorous growth. According to Bryant, the tree is hardy in Northern Illinois, notwithstanding the growth is checked by the severity of the winters. Though

four or five feet from the surface is of double the diameter that it is above. As it grows in the swamps, the trunk is clear of branches for the greater part of the height, and bears at the top a flattened, wide-spreading head. But in cultivation, with abundance of room to develop, the trunk is well-clothed with branches, which form a handsome pyramid of verdure. The foliage of the tree is especially light and graceful. The small leaves, not exceeding an inch in length, are arranged along the slender branches in two rows, like those of the Hemlock (hence the specific name, *distichum*, two-rowed). The leaves, shown in figure 1, are of a peculiar light and tender green color. To look up at the bright sky through the spreading branches of a cedar swamp, presents a play of colors long to be remembered. In autumn the leaves turn to a dull red color, and soon after fall. The cones of the shape shown in figure 1, are about an inch in diameter and contain numerous small seeds with narrow wings. A marked peculiarity of this tree is shown in figure 2. When, in its native swamps, having reached the height of twenty to twenty-five feet, there arise from the roots numerous woody, conical excrescences, which in old trees are produced at the distance of thirty feet from the trunk. These are popularly known as "Cypress knees." According to Bartram, these are four, five, and even six feet high, and from six inches to two feet in diameter at the base. They are covered with a smooth bark, and are always hollow. In localities where they occur, these "knees" are made use of as bee-hives,

elastic and easily worked, it is regarded as superior to that of any of the pines, and when obtainable, is preferred to the White Pine for all the uses for which that wood is usually employed. The wood is remarkably durable, and is highly valued for fence-posts. Shingles made from it have lasted forty years, and the shingle manufacture is an industry of considerable importance. Hogsheads for sugar and molasses are made from the wood. The timber has so many valuable qualities that experiments should be made to ascertain how far North its culture may be profitable. As an ornamental

NEW GERMAN PANSIES.

tree it takes a place in the front rank. The tree is raised readily from seed, and grows rapidly while young. Several years ago, Mr. A. S. Fuller suggested to grape-growers, that they could provide themselves with excellent and durable stakes, by sowing the seeds of this tree. A tree for sometime grown in the nurseries as the Weeping Deciduous Cypress (*Glyptostrobus pendulus*), and highly valued for the lawn, and as a street tree, is now regarded as a form of our Southern Cypress.

The Pansy—Why Not More?

If there is a generally popular flower, it is the Pansy. In the old gardens it was something like a weed; the plants from self-sown seeds produced a few small flowers, quite unlike the improved sorts of the present day. The popularity of the Pansy in England, is shown by the fact that it has some twenty common names. Some of these have found their way to this country, and we have the flower known in old gardens as "Hearts-ease," "Johnny Jump Up" (corrupted to Johnny-jumper), "None-so-pretty" (often "Nancy-pretty"), and some others. Whether our improved Pansies were derived solely from *Viola tricolor*, or by crossing with other species, is a point upon which florists are not agreed. It is of little consequence so far as their cultivation is concerned. Our climate is not favorable for the cultivation of the Pansy. If the seeds are sown in the open ground in spring, by the time the plants are large enough to flower, the weather is so hot that, no matter of how good a strain the seeds may have been, the flowers will be starved and small. To have fine results, we must have our plants ready to flower either before hot weather in spring or after the intense heats are over. Consequently, for the early bloom, we must sow the seeds in a window-box or frame in March, and for a late flowering, the seeds should be sown in a partly shaded place in August or September. To have good Pansies, we must have rich soil, and whether raised in spring or fall, the seedlings can hardly have soil that is too rich. The catalogues offer different strains of seed. A catalogue before

Fig. 2.—A LARGE SOUTHERN CYPRESS TREE WITH MANY "KNEES" (*Taxodium distichum*).

belonging to the conifers, this Cypress is not an evergreen, but, like the Larch, sheds its leaves in autumn. In its native swamps the tree reaches one hundred and twenty, and sometimes, even one hundred and fifty feet in height. The trunk is remarkable for having an immense base, which for

buckets, troughs, and other domestic utensils. Of what use these "knees" are to the tree is not known; they have never been found to sprout, and thus serve to propagate the tree. The wood of this Cypress has a fine grain, and when exposed assumes a pleasing, reddish tint; being strong,

us of a German specialist, gives some twenty distinct varieties that he has produced. We can only say, get good seeds and give good culture. Though usually treated as an annual, the Pansy is really a perennial. Any plants producing especially fine flowers, may be readily propagated and kept in cultivation as long as may be desired. The side shoots of thrifty plants, taken as cuttings, will strike root readily, and soon form flowering plants. Those who wish to excel in Pansy culture, will find it best to grow the plants in cold frames, where they may be protected from the severity of our winters, and be shaded from the intense heats of summer. The engraving shows the general appearance of what are known as the "New German Pansies," which present a great variety of strikingly beautiful colors. The Belgian Pansies, with large and beautifully marked flowers are also very fine. We know of no other flower that promises the cultivator such rich returns, with little labor, as the Pansy.

A Good Word for the Parsnip.

The parsnip is far from being popularized, though much older than the potato. It is a prime cattle food, good for beef and milk, and greedily eaten by swine. Potatoes are everywhere; they will grow about as plenty as corn and wheat. But the parsnip is the exception rather than the rule, even upon the farmer's table. A small patch is raised, of a busbel or two, if raised at all, to be dug in the early spring for a change of diet. It is a wholesome and appetizing vegetable, and could be used to advantage for half the year. We begin to use them fresh dug from the bed in October; and before the ground freezes them in, lay in a store of several bushels for winter use. In the spring we dig the reserve, and have parsnips until June. They are a dainty dish, stewed, and still better partially boiled, and then fried brown in long slices. A good crop can be had sown any time before June.

A New Branching Broccoli.

When we see, as was the case last spring, Brussels sprouts all the way from France offered in our markets, and know from our own experience that these are as readily raised as any other kind of cabbage, we think it time that our market gardeners should wake up and supply all needed garden products of home growth. It is almost ridiculous that Brussels sprouts should be imported to supply the demands of the New York market. Another form of cabbage which our gardeners almost ignore, is Broccoli. This is far more certain to head than cauliflower, and is by many esteemed as equal to

THE BRANCHING BROCCOLI.

that form of cabbage, usually so difficult to raise. Broccoli is common in European markets, and though we have not known of its importation, we should not be surprised to meet with imported Broccoli on the market stalls at any time. Among the

Broccolis are some white varieties that can hardly be distinguished from cauliflower, though the hardest kinds have a more or less purple color. A new variety has recently met with favor in France, called Branching Broccoli (*Broccoli branchu*). This, instead of forming a compact head, like the Broccolis, pushes out shoots as shown in the engraving. These shoots are cut while still tender, and before the flower buds upon them expand, are cooked in the same manner as asparagus, and are highly esteemed. The plant is also called the Asparagus Broccoli.

Lettuce Mildew.

Mr. Gus. Knock, Detroit, Mich., is troubled with a rot, affecting lettuce in the green-house and hot-beds. He writes us: "It started about six weeks ago at a time when we had no sunshine for two weeks. When warmer weather came it stopped spreading; but is now starting again on the larger lettuce. It makes a kind of web."—Mr. K.'s trouble is a mildew, from which market gardeners in some localities have suffered severely. This mildew is a near relative of the one infesting the grape-vines. When the mildewed lettuce is examined with a hand-lens, the white substance is seen to be a minute forest of small stems and branches. The mildew threads run through the substance of the lettuce leaves, afterwards come to the surface and form the branches, upon which multitudes of spores are borne. The mildew robs the lettuce of nourishment and causes it to decay. The infested leaves soon drop and become a rotten mass. Flowers of Sulphur has proved an effective remedy for the grape-mildew. This would doubtless help in staying the ravages of the lettuce mould, but the foliage is the portion eaten and, unless thoroughly washed after dusting with sulphur, it would not be agreeable to the taste, to say the least. Lime sprinkled upon the mildewed plants has proved effective. Several large lettuce-growers have found it to their interest to give up growing this crop for a few years, until the germs

of the mildew were eradicated from the soil by starvation. It is a well-known fact, that all these mildews are plants of a low order, and continue their species by the production of countless spores. These spores perform the same physiological function that is assigned to seeds among other plants. Mildews thrive in a warm, moist atmosphere, conditions which obtain in a green-house or hot-bed. In general, the circumstances most favorable for the rapid growth of garden and field crops are the best for mildews. The same is true of rusts and smuts too frequently infesting the wheat, oat, and corn-fields. Much, therefore, depends upon the weather, and this is not under man's control. The best that can be done is to use all possible preventive measures. If the hot-bed or green-house is foul with mildew, or other fungus germs, let it be thoroughly cleaned. With a hot-bed it will probably be the quickest way to build a new one on clean ground. The problem of how best to meet and conquer the many fungus pests of the farm and garden is a serious one. The rusts, mildews, moulds, smuts, blights, etc., are so very

minute and hidden from ordinary sight, that their destructive work is usually done before the presence of these microscopic pests is observed.

Liver-leaf—or Hepatica.

One of the earliest flowers to be met with in rich woods in spring, all the way from Maine to Florida, is the Liver-leaf. It is sometimes called Liver-wort, and unfortunately so, as that name properly belongs to an order of flowerless plants. The Liver-leaf has long been known as Hepatica. The ancient "root and yarb" doctors supposed that plants indicated by some character, the diseases they would cure. Thus a plant with hard, strong seeds would be good for stone in the bladder; another with peculiarly speckled leaves, was for lung-diseases, and

THE GREAT HEPATICA (*Hepatica angulosa*).

the Liver-leaf, having a fancied resemblance to the liver in shape, was called *Hepatica* or Liver-leaf. It should be said by the way, that this modest little plant is quite harmless, and was never known to interfere with the liver of any one. Those eminent botanists, Bentham and Hooker, in their great work revising the genera of plants, finding no reason for keeping *Hepatica* as a distinct genus, have united it with *Anemone*. In a popular article we speak of the plants as Hepaticas, as they will long be known by that name in garden literature. As met with in the woods, the Liver-leaf has a tuft of leaves which, in the most common species, have three blunt lobes, *H. triloba*, but in some localities the lobes of the leaves are pointed, and this is regarded as a distinct species, *H. acutiloba*. The flowers, appearing soon after the snow melts away, have a peculiarly bright and cheery look. In the wild plants they are usually pale blue, but they present considerable variety, from pale purple to white, and occasionally pink flowers are met with. The common Liver-leaf (*Hepatica triloba*), is a native of Europe as well as of our own country, and European

florists have double forms in all colors from white to dark blue. Anything more beautiful than these double varieties is difficult to imagine. The com-

Fig. 1.—HOUSE COVERED WITH CREEPER.

mon single Liver-leaf is worthy of cultivation, on account of the earliness of its bright flowers, while the double ones are most exquisite, and well worthy of the trouble required in selecting for them a partly shaded place. Still more beautiful than our native species is the Great Hepatica, as it is called in English gardens. This (*H. angulosa*), is a native of Central Europe. The plant, its aspect at flowering being shown in the engraving, is much more robust and larger than our common species. Its flowers on strong stems, are twice the size of the other, and of the most "heavenly" blue. Some plants that had been kept in a cold frame during the winter, bloomed most satisfactorily with us this spring. It does not appear difficult to manage, and we hope it may prove to be a plant that we can commend for general cultivation.

The Use of Vines and Climbers.

No other woody plants can be made to produce ornamental effects so quickly as the various climbers. Their use upon porches and verandas as well as upon the house itself, has been frequently advocated in these columns, and we now would illustrate their employment in the grounds and in several ways as suggested by Mr. Elias A. Long. Very full lists from which to select are given in the

Fig. 2.—BITTERSWEET ON VERANDA.

catalogues, while two of the very best, so far as foliage is concerned, may be had without any expense beyond that of digging, as they are common over a large portion of the country. The two vines referred to are the Virginia Creeper (*Amp-*

Fig. 3.—VINES ON GATE POSTS.

lopsis quinquefolia), already planted to some extent, and the Climbing Bittersweet or Wax-work (*Celastrus scandens*), a vigorous grower with rich, dark-

green foliage, and showy berries. This is a valuable climber, but is rarely seen in cultivation. Figure 1 shows how a very plain looking house may be improved by planting a Virginia creeper; figure 2 represents a veranda, along the edge of the roof of which a climbing Bittersweet has been trained. It may be well to give a caution here against allowing this vine to run upon trees. It winds itself around the branches with such force as to constrict them and check their growth, and if not removed will ultimately kill them. The manner in which vines can be used to cover gate posts is shown in figure 3, where, by the aid of the shears, the caps to the posts are kept in a rounded shape. A very pleasing fence to separate the ornamental portion of the grounds from the vegetable gardens and for other uses, is suggested in figure 4; posts are set at the desired distances apart, and connected by strong galvanized wire, and a Virginia creeper planted at each post. A little care given occasionally to training the vines along the wires will soon result in beautiful garlands of verdure. Figure 5 shows an archway leading to another part of the grounds. The frame-work of the arch may be made of saplings or other materials, which the vines will soon cover and conceal. The manner of draping a rustic archway of rough stones is illus-

Fig. 4.—A VIRGINIA CREEPER FENCE.

trated in figure 6. A very effective arbor may be made by constructing a frame or skeleton, as in figure 7, supported by posts at the corners. A vine at each post will convert the structure into a picturesque and pleasing embellishment. Such a frame-work for an arbor needs to be made strong, as it will have to support a great weight of foliage in summer, especially during rains.

Pruning and Thinning in the Pear Orchard.

BY A PRACTICAL GROWER.

It requires more common sense than art to prune properly. It is foolish to endeavor to make trees of many different varieties, conform to one style of growth. A tree, which is spreading in its nature, can not be made to adopt a pyramidal form. Remove interfering and dead branches, and shorten in wherever necessary. A little practice will soon enable a careful, intelligent man to do the work properly, and it is seldom that much wood need be cut away, especially if the pruning has been regularly done every year. To make the head more shapely or better balanced, it may be necessary to remove one or more limbs. This should be done with a fine, sharp, saw, after which cut the wound smooth and clean with a sharp knife, and cover it with a thick coat of good paint, to prevent bleeding, and to protect it from the influences of the atmosphere. Always use sharp instruments, and make clean cuts. As a rule, pruning shears are preferable to a knife. Carry a small stone in the pocket, for sharpening the knife or shears when the edge becomes dull. Thinning the fruit is most important. It costs no more to market a basket or crate of choice fruit, than that of inferior quality, while the price of the former is very much higher, and the sale quickly made. Nearly every fruit tree, when growing vigorously, sets more fruit each bearing year, than it can possibly perfect, and if the trees are permitted to carry it all, not only will the fruit be inferior in size and quality, but the trees may be injured. By thinning out the fruit properly, nearly or quite as much fruit in weight or measure, is secured, while the size and quality is of the best.

Make three careful thinnings of the fruit. The first thinning is done about a week after the blossoms have fallen, removing about one-fourth of the fruit, the smallest being taken. Two to four weeks later, the trees are again gone over, and one-fourth of the remaining fruit removed, as before, selecting

Fig. 5.—AN ARCHWAY OF VINES.

the poorest and smallest. Three or four weeks later, about the same per cent of the poorest specimens are removed. Leave enough fruit on the trees to make a good, heavy crop. Those who have never tried thinning out fruit in the orchard, will be much surprised at the good results.

Edgings in the Flower Garden.

The old-fashioned box-edging, with which the outlines of beds were formerly marked is now rarely seen. In northern localities it dies out in a severe winter, and unless taken up, divided and re-set, it soon has an overgrown, shabby look. An excellent edging for a bed in the lawn, is ivy—the true European ivy. It may be kept pegged down closely and neatly trimmed, and forms, with its dark-green, a fine contrast with the grass on one side, and the flowers in the bed on the other. Another climber was used with very good effect on the grounds at the Centennial Exhibition—the Gold-netted Japanese Honeysuckle. This holds its

Fig. 6.—A RUSTIC ARCHWAY.

variegation admirably, and if trained on a low wire frame, makes a very showy edging. Another excellent edging plant is the Japanese *Retinispora plumosa aurea* of the catalogues. It grows readily from cuttings, and bears any amount of clipping. There are also some other forms of Arbor-vitæ, to

Fig. 7.—A CHEAP SUBSTANTIAL ARBOR.

which the *Retinispora* really belongs, that may make serviceable edgings. The main point is to have a pleasing shrub, that will not be injured by the necessary pruning.

A Kitchen.

J. P. ROBERTS, PROFESSOR OF AGRICULTURE, CORNELL UNIVERSITY.

Among the many valuable suggestions for planning houses, given by the *American Agriculturist*, I have seen none for a kitchen complete in itself, that is, including pantry. I send a description of one which has been in use sometime, that appears about as near perfection as we can get anything. It is twelve feet square, exclusive of cupboards, has one hundred and forty-four square feet of shelving, all protected by doors from flies and dust; all within easy reach, and so divided that oranges and butter, milk and kerosene, may be kept separate. It is arranged to economize both steps and room, and have everything convenient. The rear entrance door *d, d*, is shielded from the outside gaze by the stairing in front of it. At the right is a meal chest *m*, with a double door cupboard above for lamps, etc., and has twenty-four square feet of shelving. The bath-room, containing the bath-tub *b*, is separated from the seat-room *o*, by a curtain. This room opens into the furnished bedroom on the right, and has an outside door and window for ventilation. At *e* in *o* are two drawers. Above the range *r*, is a large galvanized hood *h*, with a ten-

PLAN OF A KITCHEN.

inch pipe entering the chimney. This is just high enough to clear the head, and carries off steam and vapors rising from cooking.* The range has a water-back for supplying hot water to wash-tubs and sink. The door, *d, d*, leads straight ahead to the cellar; turning to the right you pass down the hall to the front door; to the left you pass through a door to the dining-room. This latter door swings both ways, and is always kept closed by springs. At *d, n*, is a dumb-waiter for bringing articles from the cellar; but when standing on a level, it furnishes a passage way by its shelves between the kitchen and dining-room, for passing dishes and food. On the right of this are two cupboards, *n, n*, with doors; these contain twenty square feet of shelving. On the left is the china closet, *c, c*, opening into the dining-room, at the dotted line. It has twenty-five square feet of shelving and two drawers. At *p* is a pump; *s* the sink, and *r* a drip board for draining dishes. Under these there is a closet for kettles, etc. On the back of them, on the other side of the wall, is a large book-case, opening into the study. At *t* and *u* are two large cupboards, built like the rest in the wall. These supply seventy-five square feet of shelving, and a place for a refrigerator.

*NOTE ON THE ABOVE.—The "Hood" over the range is a very good thing in theory, and sometimes in practice. We have seen them frequently, and found them failures in most cases, except where the escape pipe is in a separate flue from the smoke pipe of the range. Unless the chimney has a strong draft, the open hood pipe checks the flue

too much. In any case a close-fitting slide or damper is needed to close the opening when starting a fire, and when from the direction of the wind or other cause, the range fire does not burn quickly enough.—ED.

Summer Notes on Dress.

The furs and woollens, which have made the long, cold winter endurable, should have been packed away weeks ago, before the mischievous little moths, whose works of darkness are so destructive, appear, which is at about this time. Moth powders, cedar shavings, tobacco, horax and camphor, are all good to pack with these winter articles, but if they are well shaken in the fresh air, and carefully folded in brown paper, or even newspapers, so well pasted that not a pin hole is left open, they are safe. Of course, some woollen clothing is needed through the summer months, in this variable climate of ours. One flannel suit is indispensable, for ladies and children, and often at the sea-shore, or by the mountains, it will be the dress most needed. The best materials are cashmere serge, and fine, smooth, lady's cloth, in *écru*, gray, golden-brown, and new shades of blue. These are used very much for bride's travelling dresses, and are tailor-made, which means that they are cut by tailors, to fit perfectly to the figure, and simply stitched, or bound with mohair braid. A vest of the same material is sometimes added, buttoned with small, flat, lasting buttons. These are imitated in the less expensive fine flannels, ottoman cloths, etc. For those who prefer, these come in stripes, checks, blocks and plaids, and are used for the skirts and sashes of children's dresses, with plain, Jersey waists, of brown, red, blue or black. Skirts of white muslin, or piqué, are worn by little girls with these Jerseys.

The various cotton fabrics, muslins, cambrics, satteens, and many others which now come in such pretty patterns, that we look at them as we look at a painting or embroidery, are expensive in the end—as the sun, and salt sea-air, will fade the choicest colors, and dampness destroys their beauty, and then the trouble and expense of having them "done up" is an important consideration. Besides the summer flannels already mentioned, there are inexpensive buntings, and nun's veiling, from thirty to fifty cents a yard, each of them a soft, thin, coarse-meshed woollen fabric in all the new shades, and are very desirable, as they will endure a long service without much care. White nun's veiling was worn very much last summer, and will doubtless be very popular this season. It can be made dressy enough for any occasion, by trimmings of silk-surah, satin, or velvet ribbons. Pale pink is also very pretty with golden-brown ribbons. Wrappers of all materials are made with a yoke, and the whole front and back gathered to it, falling loosely to the floor. This is comfortable, and for a lady's own rooms desirable, but it has too much the appearance of undress, and to walk through the street, even in a quiet, country town, in this costume, as we have seen some do, is, to say the least, unlady-like. Bonnets are little changed from last year. Figure 1, shows a child's brown straw hat faced with golden-brown velvet, loops of golden-brown ottoman ribbon on the left side with a small

Fig. 1.

Fig. 2.

bunch of dandelions. A child's mixed straw hat is shown in figure 2. It may be either blue and white, or cardinal and white, faced with velvet to match; bows of ribbon and two small wings trim the outside. Figure 3 shows a lady's black chip bonnet, trimmed with black and gold-colored ostrich tips. It has black lace strings with gold spangles. The small capote, or little, round, close-fitting bonnet, is so becoming that ladies do not like to give it up, even for the sake of "a change." It should match

the walking dress, and the trimming of flowers may be so well chosen, that it can be changed from one to another foundation to suit the dress. It would seem that every known flower, leaf, or grass, is represented artificially. Many that are unknown, must be the creation of artists, whose utmost skill must fail in efforts to compete with the great Father, who gave the flowers life. These are bunched together on the top of the bonnet, or a little to the left side. Among the novelties for trimming are bunches of garden vegetables and fruits, plums, apples, etc. Ribbons are used two inches wide for strings. The fronts have puffs of satin or velvet, and some have wreaths of fine flowers all around. Gold and silver tinsel and spangles are used on black lace bonnets with good effect. Gilt wire frames are used also. Hats are little worn by ladies beyond forty years of age, excepting shade hats. They are of a high crown shape, with round, flat brim, and are trimmed with a bunch of feathers or flowers, on the left side. Some are turned up on one side. Bonnets and hats are of all colors and some straws are gilded; and bronzed. Those trimmed with black lace and flowers are very pretty. Jet, for all trimmings, is worn more than ever. There are exquisite patterns of jetted net, for scarfs, vests, hasques, and also for sleeves, and open fronts to black silk dresses. The basques have of course a silk lining, which may be high or low in the neck. Belts are worn with round, full waists, for wash dresses, with clasps of old silver jewelry, to represent old silver coins, which are very fashionable in pins, collar-buttons and bracelets. Another old fashion revived is mahogany furniture, and many old, rich articles, long considered "out of date," will be found of great value, as this wood, like a lovely character, grows more beautiful with age. ETHEL STONE.

Fig. 3.

Fashions in Letter Paper and Cards.

Though plain white writing paper, especially the heavy English kind, is not entirely out of date, very many prefer the tinted, or with an odd design in the corner, and sometimes covering the entire outer page, as a fine-spun spider's web, and there are dozens of styles to select from. "Ragged-edged" paper, which has had a run for a year or more, is still seen, but "scorched paper" is newer, and promises to become very fashionable. The edges look as if held to the fire until slightly browned. This is more curious than pretty; but eccentricity rules the hour, and anything novel takes at once.—"Wood paper" is another popular style, imitating the grain and color of hick-bark, maple, pine, and other woods. This has the head of some animal on both sheet and envelope, as a deer, dog, or horse.—"Robin-egg-blue" paper is very tasteful, and often has painted or stamped in the upper left-hand corner a pretty little bird's nest containing four tiny eggs, with a robin redbreast perched on the side. But the daintiest design of all is a silver four-leaf clover with an ordinary pin run through it as though pinning it to the sheet.—Vellum paper is the handsomest and most expensive of any, and is a pleasure to write upon, while the vellum envelopes are exceptionally fine, particularly for invitations. They are now white, and are bound with delicately tinted satin ribbon, which is tied in a knot, and sealed with wax of the same shade. Fashionable people now always seal their letters, or more frequently apply the imitation crimson seals with an initial. These are made of paper waxed over, and come by the box. These are much less trouble than the old-time candle, wax and seal, which required considerable skill and practice, while these fasten a letter securely and give a style to the epistle.

Note cards are larger than formerly, and fold over, with a lap like envelopes; but those for af-

ternoon teas, are six by four inches. They are unique in smoke color, with a gold kettle in one corner and clouds of steam pouring from the spout. On the smoke is printed in zig-zag letters:

"Come to tea
At three
And see me."

Another pretty design for these "kettle-drum" invitations is a gaily illuminated cup and saucer, with "five o'clock tea," inscribed underneath. The date and residence are written in the right-hand corner, and the hostess' name in the left.—Visiting cards for ladies are very large now, and those for gentlemen very small. The name is engraved in the plainest script, and the address and reception-day placed in the lower right-hand corner.

Pretty *sachets* come for perfuming writing-paper, made of rose or violet powder, sprinkled in a fold of cotton batting, and covered with two contrasting shades of ribbon, with a bow in one corner. These are questionable luxuries; as a general thing, scented note-paper is now considered vulgar.

Cockroaches and Croton Bugs.

The great pests of the house-keeper, especially in cities and seaport towns, are the cockroach and the Croton bug. Many suppose that the latter, from its smaller size is the young of the other, and we have often been asked if the two are not different forms of the same insect. There are several cockroaches, some of which lead an out-door life. The common cockroach is supposed to have come from some part of the East; its native country is not certainly known, though naturalists have named it the Oriental cockroach (*Blatta orientalis*). It infests ships and is thus carried all over the world. In England it is generally called the Black Beetle, though it is not closely related to the beetles. Cockroaches feed upon almost every animal and vegetable substance, and are very destructive. Articles of food that they do not devour they render ill-smelling and worthless. They give off by the mouth a dark-colored liquid which has a most disgusting odor, and this is imparted to articles kept in places when the insects are numerous. Though universally detested, the cockroach has some things said in its favor. It is very fond of another domestic pest, the bed-bugs, catching and devouring them with avidity; on this account they are sometimes tolerated on board ships as the lesser of two evils. The female insect (fig. 2), is distinguished from the male (fig. 1), by the imperfect development of her wings; the engravings show the difference in this respect. The manner the cockroach deposits its eggs is quite different from that of other insects, and is an interesting point in its history. For insects to cement their eggs together into a mass, after they are laid, is not unusual, but the female cockroach deposits hers already inclosed in an envelope or egg-case.

Fig. 1.—MALE COCKROACH.

This, which is shown at *a* and *b* in figure 2, is about three-eighths of an inch long and half as wide. Its shape has been likened to that of an apple turn-over; it contains sixteen eggs. The female carries this case about with her for several days after it is laid, and at last, finding a suitable place, she glues it fast and leaves it. A few days after, the young insects are hatched and they make their escape at the straight edge of the case. In their early life the cockroaches are white, and do not assume their regular brown color until several days old. The insect called Croton bug in this country, it having become numerous in New York City soon after the introduction of Croton water, is in England known as the field-cockroach, as it lives out of doors as well as in houses. In Russia, Croton bugs are known as "Prussians." Its native country is uncertain, though its scientific name *Blatta* (*Ectobia* of some)

Germanica supposes it to be German. It is much smaller than the cockroach, and deposits its eggs in a similar manner, the egg-cases being only one-fourth of an inch long; they contain thirty eggs. Both these insects like dark, warm and damp places in which to hide, and the introduction of water into houses, especially where hot-water pipes run to every story, has greatly increased the number of such retreats and aided in the multiplication of these insects. Country houses may be freed of both insects with little difficulty, but city house-keepers, if they kill off all that are in the house at the time, will soon have it restocked by the neighbors. Various poisons for destroying the insects and different traps are in use, but nothing is so effective as Pyrethrum or Persian Insect Powder. This should be plentifully blown into every hole, crack and cranny. It will drive the insects, young and old, from their hiding places, and in a few minutes they will drop to the floor, some will die and others only will be stupefied, and if given time will recover, hence all should be swept up and burned within a few hours. Another application of the powder should be made in about a week for the benefit of those that escaped, or may have hatched since the first. There is no difficulty in clearing an isolated house of these pests, if the use of the powder is followed up as long as any of the enemy are seen. All boxes, trunks and parcels brought into the house, especially those from a city, should be examined for these insects to prevent the founding of a new colony.

Fig. 2.—FEMALE COCKROACH AND EGG-CASES.

The Back-Yard.

EBEN E. REXFORD.

Many back-yards are abominations to the eye and nose. One finds in them all sorts of litter and refuse from oyster cans to old boots. Here the slops of the kitchen are poured to increase the odors which ought to warn every thoughtful person of the malarial influence breeding there, to break out eventually in fevers, or diphtheria. If any member of the family dies from one of these diseases, his death is probably lamented as a "mysterious dispensation of Providence," but the minister should say if he were to visit the back-yard, that death was caused solely by a violation of hygienic laws. A very strong argument against a dirty back-yard, is the spirit of deception which it is apt to foster in the young members of the family, for it is a constant deceit to present a clean and attractive front-yard to the gaze of the passers, while the back-yard is not fit to be seen. Children should be taught to be clean for the sake of cleanliness, and not because outsiders are likely to criticize them. The best plan is to have a hogshead or large box fitted up in one corner of the yard, and make it a rule to throw into this old cans, boots, broken dishes, and all such rubbish, and when there is a great accumulation, to bury or burn it. Do not allow anything to be thrown about. Have drains made to convey all slops entirely away from the house. Make good walks, and let the ground have a fine covering of grass, not weeds. Put up strong supports for the clothes line. Keep the fence in repair, and plant currant bushes near it. Set vines about the refuse barrel, and train them over it until it is hidden. If you have a receptacle for ashes, let it be something which can be shut up, not a row of old barrels to offend the eye, and give out a cloud of ashes every time the wind blows. Make it a rule to have the back-yard at all times as clean as the front one.

A VERY FINE OMELET.—Stir a tablespoonful of flour into one-quarter tumbler of milk to a paste, and mix this with three-quarters of a tumblerful

of boiling milk, adding a teaspoonful of salt and a tablespoonful of butter, then set it aside to cool. Mince a little ham, and to each two teaspoonfuls add a teaspoonful of finely chopped parsley, and add it to the milk. Beat the yolks of six eggs very light, stir into the thickened milk, adding finally the whites of the eggs beaten to a froth. Cook in a greased skillet or pan on the stove.

Wall Cabinet.

Mr. "W. J. E.," Barclay, Kans., sends us diagrams of a cabinet of his own construction, and writes: It is very easily made by any one having a scroll

Fig. 1.—A WALL CABINET.

saw. It has a more finished appearance than the one given in January (p. 24), and may suit some better. The shelf above, four inches wide, is convenient for bric-a-brac, or any small articles. The cabinet may be of walnut or any three-eighth-inch wood. Length of back and sides thirty inches, width of sides seven inches. Length of shelves

Fig. 2.—ORNAMENT ABOVE DOOR.

twelve inches, with shoulders one inch long and one inch wide, having slots cut for pins, figs. 2 and 3. Ornament over the door two and a quarter inches wide.—The door is in one piece, sawed in panels with strips screwed to back to strengthen it and hold glass. One light of glass, ten by twelve, placed on back of the door is much more convenient than several small lights, and equally as good. All is fastened together by the wooden pins, except the back to door.—To lay out the ornamental pattern, cut a card or small piece of pasteboard in shape of an acorn or leaf and mark around it; you will then get the designs all alike.—The size may be changed to suit taste or convenience,

Fig. 3.—FORM OF SHELF.

More than Strawberries and Cream.

AGNES (CARR) SAGE.

"Oh, Flora don't!" exclaimed little Edith Raymond, with a distressed face, as she and her sister stood before the dressing-case in the spare bedroom, where they had come to view their new embroidered muslins in the long mirror.—"Why not?" asked Flora, turning round and round a sparkling diamond ring that she had taken from a small jewel casket.—"I think cousin Emily would lend it to me if she were here, and I should so like to wear it to the festival."—"But you might lose it or something," urged Edith, "and that would be dreadful, for you know how much our cousin thinks of that ring; she hardly ever takes it off, and must have forgotten it. Put it back, Florie."

But Flora hesitated, and consequently was lost.—"Nellie Barnes is so proud of that pearl her grandfather gave her," she said, "I would like to show her other people can also have nice things, and we are to be at the same table. I shall only borrow it, and cousin Emily need never know it, for she will not be back until to-morrow. That is," she added, "unless you see fit to tell her."—"I am not a tell-tale!" cried Edith, rather indignantly, and her countenance wore a troubled look as Flora hastily donned her hat and gloves, and ran down stairs with the ring still on her finger. But Edith had to hurry, and her disturbed thoughts were somewhat dispelled by her father, who met them at the door and handed each girl a bright two dollar-and-a-half gold piece to spend at the Fair.—"Thank you, thank you, papa!" they both cried, "we can buy lots of pretty things with this."—"See that you make good waitresses, and do your duty by the church," he said, and with a laughing rejoinder they ran gaily down the steps.

The Strawberry Festival for the benefit of the church was the great event of the summer in Blissville, in which old and young were all interested, while the girls considered it an honor to be chosen to serve behind the tables. This year the Raymonds were very happy, Flora having been selected for the refreshment table and Edith for the floral bower.

"I am so glad it is such a pleasant day," remarked the latter, looking up at the blue sky, "and the roses and strawberries are just in their prime."—"And it is so warm, we shall sell quantities of ice-cream," added Flora, "but do look at those forlorn little wretches!"—The objects thus described were a sorrowful boy, with a pair of large, mournful, dark eyes, who was patiently turning the handle of a decidedly squeaky hand-organ, and a little brown monkey in a red coat, hopping briskly up and down to the doleful strains, occasionally stopping to circulate his small cap among the spectators gathered around.—"Poor things!" cried Edith, who was very tender-hearted. "I must give them a penny," and she darted into the crowd and dropped a coin in the tiny hat.—"You will be rid of all your money before you get to the festival," said Flora, as she came back flushed and breathless.—"No, indeed, I have my gold piece safe, and they did look so wretched I believe that boy is half starved."—"Nonsense! but here we are at the school-house and you must turn your mind from rags and monkeys to strawberries and cream."

A large room on the ground-floor of the village academy was the scene of the festivities, and it appeared very gay and attractive as the girls entered. The hall was decked with flags and evergreens, and fragrant with the odors of a thousand flowers, massed in the picturesque bower in the centre;

while the tables were hardly less tempting with their display of fancy articles, beautifully frosted cakes, mounds of luscious scarlet berries, and pyramids of ice-cream. Flora was instantly taken possession of by her schoolmates and borne off to the refreshment board, where she soon had her hands full dealing out cream to the juveniles, who considered it the greatest treat of all. She had almost forgotten her borrowed plumes when Nellie Barnes, who was assisting her suddenly exclaimed: "Why, Florie, what a lovely ring! Where did you get it? Is it yours?"—The words brought the other girls crowding round to admire the stone, and fired a perfect blast of questions upon Flora, who found their inquisitiveness more than she had counted upon. She was ashamed to confess how she came by it, and parried the inquiries as well as she could, saying with a laugh: "Don't you wish you knew?" and "whose should it be if not mine? Do you think, Nell, you are the only one that can have

"bosom friend," for the coolness increased and one thing led to another, until by evading both girls were chillingly polite, never addressing each other when it could be avoided, as is the fashion school-girls have of showing their displeasure.

Edith, meanwhile, was the merriest little flower-fay in the room, fluttering about the hall with her dainty nosegays, and selling more bouquets by her pretty coaxing manner and silvery tongue, than for the beauty of the flowers themselves. She was a general favorite, and had a bevy of boys and girls in her train wherever she went.—"I have sold all my flowers," she cried, about eight o'clock, coming up to her sister, "and oh, I have had such fun! but Florie, please lend me fifteen cents? I will pay it back out of my next week's allowance."

"What have you done with all your money?" asked Flora coldly, "you had as much as I did."—"Let me see," considered Edith, counting upon her fingers. "I bought a pin-cushion for mamma,

A PRECIOUS DISH OF STRAWBERRIES AND CREAM.

Drawn and Engraved for the American Agriculturist.

a new ring?" although she felt at the time this was uncomfortably like a fib, and she had always prided herself upon her truth and straightforwardness.

"It is a beauty!" said Minnie Bell, "and quite throws Nellie's into the shade."—"But I don't make any mystery about mine," said Nellie, vexed by the remark, "and I am sure it is quite handsome enough for a little girl. My mamma would not allow me to wear diamonds."—"Sour grapes!" sneered Flora, turning away to supply a call for cake, but she sadly felt this disagreement with her

and an apron for nurse, some candy for little Dottie Ellis, and a bunch of violets for poor lame Ned Carter. I believe that is all, except a few grabs I took in the grab-bag, and a glass of lemonade. But I haven't a cent left, and I want to get some strawberries and cream for that boy with the monkey. He is standing right outside the window, looking in with such a wistful face."—"Well, I think you have thrown away enough money," said Flora, "and I shan't encourage you in it. For all you know, that little tramp may be a thief and

will run off with the spoon. But I will pay for a plate of cream for yourself if you like it and have had none."—"I don't want it for myself," said Edith, almost crying, "and I think you are very heart-hearted, Florie," at which Flora turned on her heel with her head higher in the air than ever.

"Hey-day, what is all this?" asked a hearty voice close by, and the little flower-girl looked up to see her uncle standing beside her.—"Oh! Uncle John, is that you? I am so glad you have come!"—"That's pleasant news!" but what can I do for you? You don't look as happy as I expected."—"I want some strawberries and cream," said Edith shyly, shaking her curls over her face.—"Is that all? Here, Flora, give us a saucer of your best French cream, and pile it up well with strawberries, mind!" while Edith's eye twinkled with mischief as her sister, with a large spoon, ladled out the cream from a huge freezer behind the table. But Uncle John gazed in amazement when, just as he expected his little niece to pop a big red berry she was sugaring, into her own rosy mouth, she suddenly seized the dish and vanished through the door-way, flinging back a merry laugh and roguish glance at him over her shoulder.

Poor little Giovanni, the organ-grinder, was quite as miserable as he looked; for he had been lured away from his parents and home in sunny Italy, and brought to a strange land by a harsh taskmaster, who sent him wandering over the country with Chieo, his little monkey and only friend, to earn the few pennies that charitable people were willing to pay him. So it was like a glimpse into fairyland this warm summer evening, when with Chieo buttoned up inside his jacket, he wandered near the brilliantly lighted school-house and peeped through the window at the gay scene.—"Ze flowers look like my own country, and ze people zey are all so happy." And a tear rolled softly down the dusky cheek. But there is a flutter of a white dress near by, and a soft voice says: "Poor boy! see, I have brought you some strawberries and cream."

With a start the little Italian turns and meets a pair of pitying grey eyes gazing into his, while two chubby hands push the plate into his, as the girl says: "There, eat it quick before it melts."—"Oh, mees, thank you, thank you," he stammers, while a brown paw darts from beneath his coat and seizes a berry. "Chieo and I tanks yon a thousand times."—"I hope they will taste good," and the little maid, like a benevolent fairy, slips away.

"But what have you got there, my Chieo?" he suddenly asked in Italian, as the monkey after a spoonful of cream took something from his mouth. "There are no stones in these berries."—"But whatever it was, the monkey's brown paw closed tightly over it, and he only chattered as he deposited it in the little bag tied about his waist and in which he carried his pennies, and thinking no more of the matter, Giovanni carried his plate and spoon to the door, and lingered for a moment to catch a glimpse of the pretty little lady with the bonny brown curls. But Edith was not to be seen, for on her returning to the hall, after treating her young protégé, she was met by Flora with a frightened face, who drew her into a corner crying. "Oh! Edith, what shall I do! The diamond is gone from Cousin Emily's ring."—"Flora!" It was all Edith could say, and she stood aghast as her sister held up the golden hoop with its disfiguring cavity.—"I am afraid to go home," sobbed the frightened girl, "and it has been the most miserable day I ever spent. I have quarreled with Nellie, almost told a falsehood, and now don't dare to look Cousin Emily in the face, and all on account of this stupid ring, which I wish I had never seen."—"Don't cry," said Edith, and we will have a search for it," and she did hunt carefully under the tables and benches, but all in vain, and it was a very sorrowful pair of sisters that wended their way homeward with Uncle John. So sad indeed was Edith, that she did not see two dark eyes peering at her from behind a tree, though an unobserved listener heard her say: "Oh! dear, I don't think I shall ever be happy until the diamond is found."

It was a long, dreary night to both girls, but Flora tossed and turned restlessly, until the morning light crept through the shutters, when she

fell into a troubled sleep. So it was a very white face she brought to the breakfast table, and Edith's was hardly less anxious.—"I shan't approve of festivals if they rob you of your roses in this way," said Mr. Raymond, observing the pale cheeks, but at that moment a maid entered to say: "A wild-looking boy was in the kitchen, who begged to see the lady with brown curls." Wonderingly Edith obeyed the summons, and in a few moments returned radiant, dragging the little Italian after her and crying joyfully: "Oh! Flora it is found! The dear little monkey found it and this good boy brought it back quite safe."—"And in amazement all listened to Giovanni's story, told in broken English.

"I laugh when I find it," said Giovanni, showing his white teeth. "And I tinke now I sell this for much moneys, and Chieo and I go home to Italy. But zen I remember ze words of ze young lady, who was so heavenly kind to us, 'I never be happy till ze diamond is found!' So I can't make her sad, and I comes right away it is day."—"It was a fortunate thing for you, Flora, that it fell into such honest hands," said Mrs. Raymond, with a reproachful look towards her oldest daughter; "for had some of our rough village boys found it, I fear we never should have seen it again," while Edith whispered exultingly: "You see he is not a thief after all."—Flora blushed but made no reply, and busied herself in preparing a bountiful breakfast for Chieo and his young master, who were soon revelling in unaccustomed luxuries.

And that was not the end, for Mr. Raymond and Uncle John interested themselves in the young lad, succeeded in freeing him from his ernal master or Padrone; and a month later the whole family went to bid him farewell on the deck of a noble steamer, bound for the land of flowers and maearoni. Clad in a neat suit and with his sparkling face turned toward home, he looked like a different being from the ragged little waif, who had mournfully ground away at his organ on the street corner; and with hearts and lips overflowing, he bade his benefactors "good-bye," but his last glance and the last wave of Chieo's paw was for the sweet little girl, who on that summer evening had come to him like a good fairy, hearing to him a "mine of wealth," buried in strawberries and cream.

An Illustrated Rebus.—THE HIGH HAT.—Make words of the seven pictures on the hat, and place as shown in the small diagram. The words when placed will form the shape of a high hat. No. 5 is made with more than one word. Nos. 6 and 7 are to be read down.

CHARADE.—Read as a rebus and the first, second, and whole word will be found as in printed charades. The answer is an article used in mid-summer.

The Doctor's Talks.

I suppose that all of the little army who competed for the Weed List Prizes are desirous of hearing more about them. To make a connected story, I must go back to September of last year. In that number, on page 419, under the heading

"HOW MANY WEEDS DO YOU KNOW?"

I asked for lists of the common names "of all you could get names for during this month and next." I said: "Please observe, what I want is, the names common in your localities, of the weeds of your place, whether on the farm or growing on the roadsides," but unfortunately failed to say what plants should be regarded as weeds. "What is a weed?" has long been a question. One of the best definitions, given many years ago, is: "A plant out of place." Another is: "Every plant that grows in a field, other than that of which the husbandman sowed the seed, is a weed." Still another is: "A plant which interferes with the cultivation of other plants." None of these definitions meet all cases, but all indicate that plants in the way of cultivated plants are weeds.

A PLANT MAY BE A WEED OR NOT.

It is not its kind or character that makes a plant a weed. Parsnip, earrot and horseradish, are examples. We know how useful all three are in cultivation, yet when allowed to grow wild, they are among our worst weeds. One of the girls was told by her father that "any plant not cultivated is a weed," and other competitors appear to have acted upon that definition, as many lists contain numerous plants not known to grow in cultivated grounds. It does not seem fair to class the white and yellow water lilies as weeds, or to place oaks, magnolias, maples, and other forest trees in this class. Finding that most of the lists contained the names of plants never found in cultivated grounds, but are merely wild plants, before any fair comparison could be made, all plants never known as weeds were stricken from the various lists. This required a careful scrutiny of every list, and consumed a great deal of time.

THE WHOLE NUMBER OF LISTS

was five hundred and eighteen, and a formidable heap they made. The letters were numbered and marked with the date on which they were received. A record was then made, giving number of letter, name of writer, Post-office, State, number of plants, plants, not weeds, and real weeds, with remarks. The lowest number given in any list is ten; there is one of thirteen, and two of fourteen, and quite a number below twenty. The largest list, Miss Peppoon's, of Illinois, has two hundred and eighty names, but as seventy-four of these are not properly weeds, the number of real weeds is not so great as in one other, though a most excellent, carefully-made list. Between the above extremes, the largest number of the lists were those recording between sixty and one hundred names. I offered five prizes in hooks, and have extended the number to nine. The names of these, who will receive their books long before they see this, are given with all needed information in the table below:

Name.	Post-offices.	State.	No. of Plants.	Not Weeds.	Weeds.
Maggie E. Berton,	Livingston,	Mo.,	250	25	225
Mamie Peppoon,	Warren,	Ill.,	280	74	206
*James F. ason,	Bellaire,	Ohio,	210	34	176
*Annie Pickets,	Gibson,	Ill.,	189	15	174
*Lucy Peck,	Newtown,	Conn.,	204	39	165
Frank J. Clough,	Tolland,	Conn.,	212	48	164
Marie L. Hoyt,	Turnpike,	N. C.,	157	00	157
William Savage,	Vega,	Iowa,	152	00	152
*William Pickardt,	Portchester,	N. Y.,	162	12	150
Elijah Harlan,	Wilsonville,	Iowa,	149	2	147

ONE MORE WORD ABOUT WEED LISTS.

Having a use for the common names for the weeds of the country, I offered prizes for the best lists. My success has been very far beyond my ex-

*Remarkably good for a boy of thirteen.

†Jennie Miles, Eliza and Eva Upp, and Annie Pickets forwarded their lists in the same envelope. Miss Pickets' list is the only one long enough to secure an award.

‡Exceptionally well written.

§I can not allow "old boys"—you claim to be thirty-two—to compete with our boys and girls. Still I thank you for your most excellent and instructive list.

¶Remarkably good.

petations. While but a few could get a prize, every one who sent a list has done me good service. The shorter lists which did not take a prize,

and if for no other reason, you should have nothing to do with them. American boys and girls should be too sensible to think that making a

Fig. 1.—THE HOPOE.

promise to be as useful to me as the longer ones, and every one who has sent one of a kind, small or large, has my most hearty thanks. There are many weeds about which I wish to ask questions, and many of you will receive applications during the season, and I do not doubt that all of you will gladly aid me.

GETTING READY FOR THE FOURTH.

Every youngster knows that there is but one Fourth deserving of being called "The Fourth," and that is the day following the third of July, often called "The day before the Fourth." I assume that every American boy, if he is any sort of a boy, will celebrate the Fourth. Celebrating, with many boys, consists in not doing those things they do on other days, or in doing something not done on other days. The usual result is, very tired boys. As there is of course to be a celebration, the way to make it a good one is given below.

BEGIN TO GET READY NOW.

"It's too early," do you say? I say "not a day too soon." In my youngster days, I had much to do with celebrations of various kinds; excursions, pic-nics, and other affairs which brought many people together. In my experience I found that those celebrations were most successful and enjoyable, for which there had been, what boys sometimes call "a good ready." Besides, there is often as much enjoyment in preparing for a good time as there is in the time itself.

The Fourth of July is our one, only really grand national holiday, and it should be made the most of, not only by every boy and girl in the great *American Agriculturist* family, but by all others in the land. The greatest enjoyment of the day cannot be had unless "ways and means" are well considered, and the plans thought over beforehand.

THE DAY MUST BE CELEBRATED,—BUT HOW?

Boys in cities and villages often begin to save up their money, months in advance, to buy fire-crackers for the Fourth. Not only crackers, but pistols, guns, and even cannon are used to make a noise and disturb people who like quiet. Why fire-crackers, those spiteful little snappers, should be used to celebrate the great American Holiday, I could never discover. They are employed in the religious services of the "Heathen Chinee," and should be left to their proper use. Besides they are dangerous,

noise, a smoke and a smell, is the best way of celebrating the anniversary of the greatest day in the world's modern history. By far the best way at least for boys and girls in the country, is to have a neighborhood celebration.

Such things do not start themselves. Let some boy ask two or three others to join him, and arrange all the plans. A most sensible celebration is a Fourth of July Pic-nic, to which each one brings his or her own provisions. The first point to decide is, the place for the picnic. A grove is best, at any rate let it be a pleasant spot. Having selected the place, invite all the youngsters in the neighborhood, taking care that not one is overlooked. Let it be understood that older people will be welcome. Some of the boys should see to putting the ground in order, moving away the brush and clearing off the rubbish; others should take charge of providing swings; every other preparation should be assigned to some one, and not be left until the last day. The object of the celebration being for every one to have a good time, the exercises should not be long or formal. The most important should be the reading of

THE DECLARATION OF INDEPENDENCE.

This gives the reasons for regarding the day as above all other days, and every boy and girl should read it, or hear it read, at least once a year. Select the reader well beforehand—one who can read distinctly, and he should rehearse his part beforehand.

Some Interesting Birds.

THE HOPOE (figure 1), is a native of Africa, and migrates to the continent of Europe in summer, and is occasionally met with in England. It is about as large as the Thrush; its long, slender bill covers a tongue which is forked at the tip and can be greatly extended; this it uses to extract the nectar from flowers. The plumage is very handsome, being variegated with rich brown and purple, black and white. Upon the head is a crest of feathers, which the bird can erect at will; the feathers of this are orange-colored, fading to nearly white with black at the tips. The note of the bird is like *hoop, hoop*, repeated several times in a low, soft tone; it is this note that gives the bird its common name. The male Hoopoe also produces instrumental music; it first draws in air and by tapping the end of its beak down a peculiar sound is given out.

THE LYRE-BIRD (fig. 2), of New South Wales, is the size of a pheasant, and is remarkable for the length and form of its tail. Twelve tail-feathers have long and slender shafts with the barbs very far apart. The two central feathers have a plume on only one side; the outer two are longer and broader than the others, and so curved that the two form a figure like the outline of an ancient lyre. The general colors are brown and black, with reddish spots on the two broad feathers of the tail. It is very shy, hiding among the brush. The Lyre-bird has a pleasing song, and is said to imitate other birds; it is by far the largest song-bird known.

The coeks are quite war-like; one traveller states that, hearing a great noise, he cautiously crawled along to learn the cause, and discovered about one hundred and fifty magnificent Lyre coeks "ranged in order of battle and fighting with indescribable fury." The Lyre-bird is unusually large for a song-bird, and it presents another exception to the usual rule among birds. Songsters are generally very plain birds; they rely upon their voice to make them attractive and do

Fig. 2.—THE LYRE-BIRD.

not need showy plumage. This bird is doubly provided, having a rich voice and fine feathers.

THE DOCTOR.

OUR RECORD OF Recent Agricultural Inventions.

Straw Cutter.—D. M. Cummings, Enfield, N. H. Feb. 5; No. 293,150. In this cutter the straw, fed between the binding roll *l*, and the flat blade *e*, is cut up by

the spiral saw *d*, from which it passes through the spout *p*, to the hard rolls *r*, which complete its disintegration. The patent covers the combination and gearing of these parts.

Stalk Chopper.—W. H. Mercer, Mercer, S. C. Feb. 5; No. 293,055. The knives of this chopper are attached to a cylinder, which is rigidly fixed to a shaft. Surrounding the knives is a slotted cylinder loosely hung on the shaft, so that when in use, the cutters of the inner cylinder will project through the lower slots, far

enough to cut the stalks as they lie upon the ground. To protect the knives when the machine has to be drawn upon a hard road, sliding plugs are placed on the ends of the shaft, and means are provided for driving the plugs into the end openings of the outer cylinder, so as to prevent its dropping and exposing the cutters.

Flood Fence.—Elizabeth S. Garrett, Downeyville, Ind. Feb. 5; No. 293,003. The engraving shows a single panel of this flood fence, the dotted lines indi-

cating the position of the parts when the fence is pressed down by the force of the current. The inventor claims the hinged panel, the anchors, the bent spring, and their fastenings.

Cultivator.—Dominicus Brix, Geneseo, Ill. Feb. 5; No. 293,979. The patented features of this cultivator lie in the means for adjusting the position of the plows. The forward standard or hanger is pivoted at its up-

per end to turn on the underside of the plow-beam. The rearmost hanger has a laterally projecting perforated bar upon its upper end, and the plow beam has a lug or bolt which engages the perforations, thus locking the plow in the position desired. By these means the

point of the plow may be turned inward or outward at will, changing the width of the furrow when plowing, and bringing the point of the plow nearer to, or farther from the row of plants when cultivating.

Harrow.—E. V. Caldwell, Harpersville, Ind. Feb. 5; No. 292,985. This is a combination harrow, capable of being adjusted to serve the purposes of a harrow, a cultivator, a rake, a pulverizer, a cotton-thinner, etc. The inventor claims the combination of the draft beam, car-

rying two sets of cross-bars, *b, b*, upon which are hinged the removable tooth beams *e, e*, with the adjusting rod *h*, and the clamp *i*. The teeth of the front beam are forwardly inclined, while those of the rear beam incline backward. The changes required for varying uses, are simple and easily made.

Rotary Harrow.—D. W. Brown, Beckhannon, West Va. Feb. 26; No. 291,113. In the engraving the driver's seat *d*, is partly cut away to expose the pivot of the draft beam, and the connections of the hitch rods *f, f*. By varying the adjustment of the guy-rods and hitch-

rods, the harrow may be made to turn in either direction, or to have no revolution. The patent covers the combination of these parts, and the shovel-carrying rear-bar and its connecting rods.

Harrow for Cultivating Listed Corn.—Byron Clark, Greenwood, Neb. Feb. 12; No. 293,227. In this harrow, a cross section of which is shown in the engraving, the beams *a, a*, and bars *b, b*, to which the teeth *d*, are attached, are secured by hinges to the run-

ners *c, c*, which are joined sled-wise by the arches *u*. The runners guide the harrow, and protect the corn from clods and earth, while the furrow is being filled by the action of the teeth. The hinged tooth-bars are so connected that the width of the harrow is variable. The inclination of the teeth is also adjustable.

Cultivator.—I. A. Smith, Dexter City, Missouri. Feb. 26; No. 294,091. The object of this invention is to secure the plow standard to the frame in such a way, that when the share strikes a large stone or other obstruction, the upper part of the standard will be automatically disengaged from the beam, and allow the share to swing out of the ground. The displaced share

drops into place again when the handle is lifted. To this end the standard is locked in position by a spring-held catch which yields to extra pressure, yet allows the standard to swing into place by its own weight, when the cultivator is lifted from the ground.

Seeding Machine.—A. Shafer, Cassopolis, Mich. Feb. 26; No. 294,158. The inventor aims to make more certain and uniform the scattering and covering of seed. To this end he attaches to any gang-

plow, the plows of which are adjustable to cut at a uniform depth, a seeding device which conducts the seed to the furrows, and ensures its regular scattering and covering. An endless carrier running continuously in the same direction, and operated by one of the traction wheels, delivers the seed continuously to the spouts.

Seed Drill.—J. H. Purdy and C. T. Welch, Belton, N. Y. Feb. 19; No. 293,671. This drill-tooth is thought by the inventors to be an improvement on

the one patented by them a year ago. They claim as new the series of hollow, inverted, truncated cones *e*, the conical scatterer *d*, suspended as shown in the engraving, the adjustable guard *m*, for preventing too great scattering of the grain during shallow plowing, and the vibrating covers *g*.

Check-Row Corn-Planter.—E. W. Quincy, Peoria, Ill. Feb. 26; No. 204,369. The inventor's object is threefold,—to arrange the parts of the machine so that the check-row line shall enter the machine at one side of, and clear the team, and pass diagonally across the machine frame, so that the progress of the team shall not be impeded by the check-line; to so arrange the seeding

mechanism that it will be operated in a direct and positive manner by the check-line; and to provide in a pivoted cup-seeder, the means for delivering a regulated quantity of seed at each discharging movement. The engraving shows vertical longitudinal sections of the machine, and the seed-dropper.

Potato Digger.—L. Habeck, Town Lake, Wis. Feb. 5; No. 292,804. The inventor converts a plow into a potato digger, by removing the mould-board, and put-

ting in its place the platform *e*, and its attachments. His patent covers the wheel *l*, with sleeves *b*, braces *h* and *k*, platform *e*, shaking-bar *f*, with its prongs, and the notched rod *g*, in combination with the usual parts of a plow-frame.

Higher Prices for Butter.
All dairymen who use Wells, Richardson & Co's. Improved Butter Color, agree that it increases the value of butter several cents a pound. It is pure and harmless, convenient for instant use, has no taste or odor, and gives a clear, golden richness to the butter. It is the very best butter color obtainable, and is not expensive. In every State in the Union the demand for it is increasing.

Stockbridge Manures.
 Prices Reduced. Standard Maintained.
The Massachusetts Fertilizer Inspector's Valuations of the STOCKBRIDGE MANURES } *Average \$44.48 per Ton*
 for the past seven years
 The Average Price for 1884 will be \$4.50 per bag, or \$5 a ton less than last year.
 In buying a fertilizer, its quality and by whom manufactured should be considered along with the price per ton. A ton of good English hay is considered by most farmers cheaper at \$20 than a ton of bog meadow hay at \$10; and for the same reason the Stockbridge Manures, which are made largely from chemicals, and are very concentrated, are cheaper at the prices asked than many fertilizers at half the price. They have stood the test of the field and State Inspectors for nearly ten years, and have been found the most *reliable* and *richest* fertilizers offered in the market. The fact that they have been well made in the past should be a sufficient guaranty of their strength and purity in the future; but, notwithstanding this, we are still under bonds to Prof. STOCKBRIDGE to maintain their standard. Send for pamphlet (mailed free), to

Milking Tubes Again.

Our attention is kindly called by a subscriber in Wilmington, N. C., to the fact, which gives us no little pain, and which we had entirely forgotten, that several years ago, one of the writers for the *American Agriculturist* had, for a time, such faith in milking tubes, that he recommended their use in this Journal. At that time there was quite a furore about milking in this way. A Scotch farmer brought out the tubes from Scotland, and said that they had been thoroughly tested there. He advertised that he had them in constant use on his own cows. He was known to be an excellent practical farmer, and hundreds of people were deceived. He did indeed use the tubes on one or two of his many cows, and the poor things' udders were swelled and gargeted. The writer experimented with them once, and the very next day one quarter of the cow's udder was inflamed. Such was the well nigh universal result. The writer for the *American Agriculturist* who endorsed the things, soon discontinued their use, but did nothing to repair the injury he had done by their advocacy. It pains us to see that very article, recommending the wretched things, reproduced by a prominent dealer in his catalogue of farm and garden implements. Our readers will please bear in mind, that we now assert the tubes to be dangerous in the extreme, liable to injure the cow permanently, and sure to do so temporarily, unless handled with the utmost care. The reason for this is that, besides the slight local irritation liable to occur from the insertion of the tubes, there is the greatest likelihood of a minute bubble of air passing from the tube into the udder. Air in the udder is a foreign body, and there appears to be no way of getting rid of it, except perhaps by means of an attack of the garget. When this comes, the chances for saving the inflamed quarter are slim. Sometimes it becomes necessary to draw the milk from a teat, when the teat is so tender and sore that it cannot be pressed by the band in the usual way. In such a case, we have found the best tube we could use to be a crow-quill. The quills of a crow's wing are small, sound and firm, and usually long enough, but in case the one selected seems too short (not less than an inch and a half long), the best plan is to cut it off a little longer, cutting into the shaft of the feather, and then carefully cleaning this out, so as to make a continuation of the tube. The pointed end of the quill is to be inserted in the teat, and this must not be cut off, but softened by moistening, and then opened by a pin or sharpened mateb. The end of the tube made in this way is somewhat contracted, and is not so likely to let any air into the udder. Still, on removing the quill or tube (if a metal tube be used), the wet finger should be placed upon the end, so as to close it entirely, and then the tube gradually withdrawn.

TO OUR READERS.

Are you receiving your paper regularly?
Has your complaint, if any, been promptly attended to?
Has any question that you have asked us been satisfactorily responded to?
Do your premiums please you?
Is there any new department you would like to have in the paper?
Do you wish for any information about the West?
Would you like to know more about Dakota, Nebraska, or Kansas?
Do not hesitate to write us freely.
Our aim is to make the *American Agriculturist* of the greatest good to the greatest number.
We wish every subscriber to feel a co-partnership interest in the paper; to feel that it is published for him; and that it is his right and privilege to ask for what he wants, and to get what he asks for.
Do not hesitate to write us at any time, upon any subject. We will endeavor to answer all your questions, and furnish you with all the information that is in our power.

We have editors in every department of the farm, garden, and household, who will cheerfully answer all questions of our subscribers.

You would be surprised to see what a vast number of questions come in to us sometimes in a single mail. But they are distributed and sent to the respective editors.

Often days of examination or investigation are required to answer the questions; but we propose to answer them just the same, no matter how much time is required.

N. B.—Questions and queries of our regular subscribers only are answered.

Our Splendid Microscopes.

The *American Agriculturist's* Simple Microscope, described so fully in the March number of the *American Agriculturist*, is giving the greatest satisfaction.

It is undoubtedly far superior to anything of the kind ever manufactured.

It is made expressly for us, and by the noted manufacturers, Bausch & Lomb Optical Company, on a design which can be obtained only through us.

We will present one of these Microscopes, delivered free, with the *American Agriculturist*, post-paid, to any new subscriber for 1884, for two dollars. Any person who is already a subscriber to the *American Agriculturist*, can have one of these Microscopes delivered for one dollar and twenty-five cents.

Our Engravings.

Never in the history of the *American Agriculturist* have we been able to present such beautiful illustrations as are now given in the paper.

Last month we secured the services of a new and most talented artist, who, with his assistants, will do all he can in the way of pictures and illustrations to please and instruct you.

We shall spare no expense in making our engravings the very best that are to be found in any similar journal in the world.

Bound Copies.

Keep your copies of the *American Agriculturist*, and have them bound whenever you have twelve of them. Should there be a missing copy when you send the numbers to be bound, we can supply another. The other day, one of our old friends dropped in to tell us that he had every single copy of the *American Agriculturist* from the very first issue.

If, when you are in the city, you will look in upon us some day, we will take you into the File Department, where you will see the volumes of the paper for very many years back, properly classified in sections.

We can supply copies of any number, of many years back, on five minutes notice.

THE OPINION OF

SIR ROBERT CHRISTISON, BARONET, M. D., PHYSICIAN TO HER MAJESTY THE QUEEN; PRESIDENT ROYAL MEDICAL ASSOCIATION; PROFESSOR AT THE UNIVERSITY OF EDINBURGH, &c., &c.

LIEBIG CO.'S COCA BEEF TONIC is a remarkable preparation. It contains the nutritive elements of the muscular fibre, blood, bone and brain of carefully selected healthy bullocks dissolved in rare old sherry wine. To be precise, each tablespoonful contains the nutritive elements of one ounce of choice beef, one grain and a half of pure quinine and two grains of iron. It also embodies a concentrated extract of coca, a South American tonic, of which Sir Robert Christison says: "The properties of this wonderful plant are the most remarkable of any known in the medical world. From repeated personal trials I am convinced that its use is highly beneficial and tonic."

PROF. DUNCAN CAMPBELL, M. D., LL. D., F. R. S., President Royal College Physicians and Surgeons, member General Council University of Edinburgh, &c., &c., says: "LIEBIG CO.'S COCA BEEF TONIC has more than realized my expectations."

PROF. JOHN M. CARNOCHAN, M. D., Surgeon-in-Chief New York State Hospitals, Professor Surgeons New York Medical College, ex-Health Officer port of New York, &c., says: "My patients derive marked and decided benefit from the LIEBIG CO.'S COCA BEEF TONIC."

PROF. F. W. HUNT, M. D., LL. D., Honorary Member Imperial Medical Society St. Petersburg, Russia, Professor of Practice of Medicine, &c., says: "LIEBIG CO.'S COCA BEEF TONIC is far superior to the fashionable and illusive preparation of beef, wine and iron."

"My practice is among women; with worn out, run down, debilitated, overworked school teachers, milliners, dressmakers, and other classes of self-supporting women, and they all require a good tonic. I have prescribed gallons and gallons of tonics, but none of them are equal to yours. It is positively the best of any which I have ever taken myself or ordered for my patients."—Opinion of Dr. S. E. Brown, 27 Columbus av., Boston, of the LIEBIG CO.'S COCA BEEF TONIC.

"I have had the most unflinching success among hundreds of my broken down and nervous lady patients by the use of LIEBIG CO.'S COCA BEEF TONIC," says Dr. George E. Clark, 801 Tremont st., Boston.

For the opinions of Prof. H. Gonlon, M. D., LL. D., Physician to the Grand Duke of Saxony; "New York Medical Journal," "New York Medical Times," "Journal of the Royal Society of Vienna," and hundreds of equally eminent physicians and scientists, send for a circular.

It is invaluable in debility, nervousness, malaria, dyspepsia, biliousness, nervous and sick headache, opium habit, shattered nerves, asthma and female infirmities. It improves appetite and digestion, enriches the blood and reinvigorates every organ and faculty. It reconstructs the most shattered and enfeebled, reinvigorates the aged and infirm, and makes sickly children blooming and healthy.

Beware of counterfeits under imitative names. Prepared only by the LIEBIG LABORATORY AND CHEMICAL WORKS CO., NEW YORK DEPOT, 83 MURRAY ST.

THE OLD RELIABLE HALLADAY STANDARD WIND MILL

27 YEARS IN USE.

GUARANTEED

Superior to any other make. 17 Sizes-1 to 40 H. Power. Adopted by U.S. gov. at forts and garrisons and by all leading R. R. Cos. of this and other Countries. Also, the

Celebrated I X L Feed Mill,

which can be run by any power and is cheap, effective, and durable. Will grind any kind of small grain into feed at the rate of 6 to 25 bushels per hour, according to quality and size of mill used. Send for Catalogue and Price-List. Address **U. S. WIND ENGINE & PUMP CO. BATAVIA ILL.**

HERCULES WIND ENGINE.

The principles of a Turbine applied to a Wind Motor. We desire to call attention to the following extracts from a private letter, illustrating the superiority of the Hercules.

"My ten-foot Hercules drives a 12-inch Burr mill, elevates all my grain, besides pumping all water for my stock. I was grinding corn to-day, the grinder making about 1,000 revolutions per minute, when a man came in, and after looking at the mill, asked if it was holed it was ground so fine. It operates in a very light breeze. All who have seen it, pronounce it the finest thing they ever saw. It is placed inside the cupola of my barn. Yours very truly,

JAMES HOSTLANDER, N. Ridgeville, Lorain Co., Ohio.

Illustrated Catalogues mailed to all who enclose stamp. Address, **HERCULES WIND ENGINE CO.,** Worcester, Mass.

THE DANA CENTRIFUGAL-COVERNOR WINDMILL.

This is the best working, and the most powerful Wind-Engine in the world, because of—first, the superior excellence of its self-regulating mechanism, and second, the better form and position of its sails. The facts and reasons which support this claim are set forth in our Descriptive Catalogue, Second Edition—1884, for which apply to

The Dana Windmill Co., FAIRHAVEN, MASS., U. S. A.

7,000 CHALLENGE WIND MILLS.

IN USE IN EVERY State and Territory of the U.S. It is a sectional wheel, has been made by us for 15 years, and has never blown down without tower breaking, a record no other mill can show. **MILLS SENT ON 30 DAYS TEST TRIAL. SEDGWICK STEEL WIRE FENCE.

Is the only general purpose Wire Fence in use, being a Strong Net-Work without Barbs. It will turn dogs, pigs, sheep and poultry, as well as the most vicious stock, without injury to either fence or stock. It is just the fence for farms, gardens, stock ranges and railroads, and very neat for lawns, parks, school lots and cemeteries. Covered with rust-proof paint (or galvanized) it will last a life-time. It is Superior to Board or Barbed Wire in every respect. We ask for it a fair trial, knowing it will wear itself into favor. The Sedgwick Gates, made of wrought iron pipe and steel wire, defy all competition in neatness, strength and durability. We also make the best and cheapest All Iron Automatic or Self-Opening Gate, also Cheapest and Neat set all Iron Fence. Best Wire Stretcher and Post Auger. Also Manufacture Russell's excellent Wind Engines for pumping water, or geared engines for grinding and other light work. For prices and particulars ask hardware dealers, or address, mentioning paper,

PROF. J. A. GOING, P. O. Box 938, New York City.

Furniture and Picture Auctions, are very frequently swindles. The sale of the effects of "a family breaking up house-keeping," often continues for months. The stranger in the city should avoid all such auctions. If he enters the place, he will find a gang of confederates ready to aid the auctioneer in making it appear that he has bid a high price for their worthless stuff. One who is entrapped in such a place, should at once go, if he has to fight his way out, to the nearest police station and enter his complaint.

Stock-Raising in Texas.

The ranchero who charged a dollar for what he called a "general description" of his spotted ponies, which did not describe anything, now proposes to teach "Stock Raising in Texas." Those who wish to know "terms and contract of just what we will do," can ascertain by sending, as before, one dollar. If young men wish to go to Texas, we advise them not to commit themselves to this man in advance, unless he gives satisfactory reference. Unlike the regular Texan, this recent comer from Ohio is rather sharp after a dollar. Will some one who has been at this ranch give us his experience?

Free Recipes at Rochester.

New York and Brooklyn have heretofore been regarded as the headquarters of those who work the "free recipe" swindle, but now, W. A. Noyes, of Rochester, N. Y., has a formula from "an East India Missionary." He, like all the rest, "felt it his duty to make it known to his suffering fellows." J. Dwyer, Knox Co., Mo., writes us on behalf of a neighbor, who is taking the stuff sent him, and does not improve, asking what we know of the recipe chap. We know just what you know. He advertised to send the recipe free of charge. The recipe, when it came, was of no use, as the stuff was prescribed under names that were unknown to druggists. Noyes knew this, and proposed to furnish the stuff himself. Your neighbor paid five dollars for some kind of roots—no one knows what. There was an intentional fraud at the outset—is it likely that the rest of the transaction will be honest?

Martin Meyer and his Lottery.

It is a long time since we heard of Martin Meyer, Jun., and his "Lottery of the City of Hamburg," (Germany), but he now is annoying our subscribers in Iowa, and other Western States, with his very voluminous circulars. We are told that this lottery was established more than a century ago. "Of little importance in the beginning, it has insensibly grown year after year, to such magnitude that its tickets are spread all over the civilised world." It must be a comfort to those who draw blanks, to know that their tickets all bear the arms of the "Free City of Hamburg." Meyer sends a "Promissory note," in which he agrees upon the receipt of the money, to send the tickets—which is very kind of him. We believe in the encouragement of domestic manufacturers, and even in such nuisances as lotteries, do not think that the foreign product should have any advantages over the home-made. Under the working of our present laws, the City of Hamburg can carry on the lottery business among us, while the City of New Orleans is shut out of the mails. Still the law is a good one, until a better can be provided.

The Various "Graphs."

There is much that seems dubious among the "Arto-" "Color-" "Pearlo-" and various other "graph" operators, who offer great inducements to persons, especially ladies, to color photo-graphs for them. They each warn people against all the others, and as we have had complaints of all of them, we last month, in order to get at the true history of the matter, asked for the experience of "our lady readers." The very first response came from a gentleman, a clergyman in Rhode Island, who for obvious reasons does not wish his name published. Wishing to do something to help out his meagre salary, he replied to the advertisement of one of the Philadelphia concerns, sending a dollar. He says: "I received circulars giving instructions how to color pictures, but so blind, that no

one could hope to succeed. The real object is, not to sell paints and materials, but to get a dollar for a 'Book of Instructions,' and the same is utterly worthless." He adds: "I read it over three or four times, to try to make sense or reason of it, and failing, gave it up. I am quite satisfied that no one could color the pictures so as to be accepted and paid for by the 'Co.'" Next!

"The Greatest Mining Enterprise in the World."

The above is the unassuming title that modestly heads a prospectus before us. It goes on thus: "See what great veins of gold, silver, copper, and lead the Atlantic-Pacific Tunnel is being steadily driven into," and all this in fancy type and displayed lines. What follows is rich reading. This Tunnel, the precise location of which is carefully not given, goes right square through the Rocky Mountains and taps below those veins which miners have been working with so much labor from above. Here there is nothing to do but shovel out the ore—and such ore! Here's richness! The reading of the accounts of the few fortunate persons who have visited this Tunnel is fascinating. When the mine gets fairly at work, the output is expected to be one hundred thousand dollars per day! We can only say, that while three thousand five hundred and seventy-eight persons hold shares, only about half are taken. The rest may be purchased of—but these are not advertising columns. Such schemes as this can only affect those fond of speculation, and who can usually stand a loss without being distressed. But how can there be loss with one hundred thousand dollars a day?

Wonderful Fruit Trees for Farmers.

A Subscriber, Washington, Kansas, writes us that tree agents are canvassing his county. They represent, as they say, great nurseries, are on a salary, and therefore bound to go according to instructions, and always do right. They claim the nursery company has many millions in the business, and cannot afford to mislead, etc. These agents have fruit in alcohol, elegantly colored plates, and photographs of wonderful plants. They warrant apple trees to produce fruit in two years, and show how this can be, as follows: "They bud on Russian crab stock two years old, with buds from bearing trees. The crab produces fruit at three years, and if the buds are from bearing trees, they must produce fruit in two years after budding." The agents also state that the peach is budded upon plum stock, and the trees are never effected with borers or "blight," and fruit every year. By cutting back two-thirds of the growth every year, and leaving only buds on the underside, a beautiful drooping top may be formed. This "weeping" condition of the peach is shown by a photograph of a tree grown at the nurseries. These men are taking a great many orders for these wonderful trees at fabulous prices. Thus the sharks prey on the honest farmers in Kansas.

How many times have we cautioned farmers and others not to invest largely in new and remarkable fruit trees, on the strength of smooth talk, and highly colored pictures.

Newspapers with an Annex.

It is coming in fashion for journals and magazines of various kinds to have an attachment or annex of some kind. This at one time took the form of a lottery, but in spite of the fact that it was called a "Distribution," or by some other name, it brought the publishers to grief when they were deprived of the use of the mails. As there are difficulties in the way of running an annex in the form of a lottery, there are indications that it will in future assume the form of

A BANK OR A LOAN OFFICE.

A few months ago, we mentioned the scheme of a Cincinnati publisher, who proposed to set aside a share of its receipts, to form a fund to be distributed in loans among the subscribers to the periodical. The Cincinnati publisher is not alone in having a banking attachment to his publication. A competitor has appeared in the

"INTERIOR DOLLAR MAGAZINE."

Like the prospectus of the other, the circular of this shows by plain figures, that but one thing is needed to make publishing very profitable to the publishers, and allow them to aid their subscribers by making them loans in amounts of one hundred to five hundred dollars—that one thing is a subscription list of some hundreds of thousands of subscribers. This scheme, which is set forth by the "Michigan Loan and Publishing Co.," with its headquarters at Charlotte, Mich., reads so much like that from Cincinnati, and uses illustrations and figures so nearly like those in the other, as to suggest that both had one origin. This more recent affair has the advantage over the older one, as it offers its loans at three per cent interest instead of four. In looking through this

prospectus, we have not been able to learn how often the "Interior Dollar Magazine" is published, what is its scope, or who are its writers. Indeed, there is an entire absence of names in the pamphlet, which shows wonderful modesty on the part of those who propose to revolutionize the publishing business.

Mr. Hart's Experience with "Magnetic Appliances."

Mr. S. N. Hart, of Southington, Conn., writes us, that in December last he received from a concern in Boston, Mass., "a belt and insoles. Their circular says: 'Bear in mind, we guarantee a cure, and will cheerfully refund the amount paid when they fail doing all that is claimed after reasonable trial.' On Nov. 13th, they wrote me: 'Yes, we will guarantee a cure, or take pleasure in refunding the money.' On Nov. 19th they wrote me: 'We guarantee to effect a cure, or refund the money.' On Dec. 4th I commenced wearing the belt and insoles, and used them faithfully for ninety-nine days. Neither my wife nor myself were able to see the least advantage from their use, and on March 5th I wrote them to refund the money (ten dollars). March 12th I mailed them another letter, stating that I should send a sight draft. I returned the belt and insoles on March 12th, and can truthfully say that I have had no reason since to think that they ever did me a cent's worth of good. The draft was returned, marked 'refused.'—We have examined numerous so-called 'Magnetic,' 'Galvanic,' and 'Electro-magnetic' appliances, and though some make a great display of 'hardware,' we have never yet seen one that could produce any electric, galvanic, or electro-magnetic curative influence. Any form of electricity to produce any effect, must pass through the diseased portion of the body and act on the nerves. None of those we have seen do anything of the kind. The appliances we have seen consist of

DISKS OF COPPER AND ZINC, OR OTHER METALS,

riveted to Indian rubber cloth. That they have sometimes been useful, we do not doubt, as a strip of rubber cloth applied closely to the skin is often very beneficial in rheumatic and other affections, and probably none the less so, if it has some metal disks attached. Very likely the alleged curative powers claimed for the various 'appliances,' is due to the cloth and not to the metals attached to it, which may serve as ornaments, and aid the imagination of the patient, as they look 'scientific.' As to our correspondent's failure to get his money back, what can he expect from one who will propose the impossible—"guarantee to effect a cure"?

We commend Mr. Hart's example to others. He has a charge to make, and makes it boldly, without adding, "please do not use my name." We can understand why, in many cases, persons should not wish to have their names appear, but in instances like the above, where there is a direct failure to comply with an agreement, and there is nothing of a delicate nature involved, correspondents should be willing that their names be given. A warning substantiated by a name and address, has far more influence than when initials only are published. Still, where our correspondents indicate a desire to avoid publicity, their wishes are respected.

Fraud at the Breakfast Table.

To the average American, coffee is as essential to a good breakfast, as is tea to the Englishman. The frauds practised by the makers of ground coffee, are many and well known. These may be readily avoided by the purchase of coffee that is not ground. It has been supposed that one who purchased the raw bean, and roasted and ground it himself, would have pure coffee. While this course avoids one set of adulterations, those which are only possible with ground coffee, it may be but a change of evils. While raw coffee is free from adulteration in the proper sense of the term—the adding of a cheaper article to reduce its cost to the seller, the purchaser may fall upon what is still worse—poisoned raw coffee. It has recently been discovered by the officers of the Board of Health of New York City, that Maracibo, Rio, and other cheap coffees, are manipulated and colored in their unroasted state, to make them resemble in appearance and color, the "Old Government Java," and that in the process there are used various coloring materials which are of a poisonous nature, and which one would not, even in small quantities, willingly take into his system. Among the coloring matters are some, which, like niter, Venetian red, lamp-black, soapstone, etc., are no more harmful than the same quantity of any other kind of dirt. On the other hand, there are employed compounds of arsenic and lead, which one would not care to take with his coffee in even minute quantities, besides the prussiate of potash and other chemicals not usually regarded as essential to a good breakfast. The cheap coffees are green, and the surface has a dull appearance, while Java coffee has a yellow color, and the surface of the bean is

smooth and polished. The articles we have mentioned are used to change the green of cheap coffees to yellow. Sprinkling the coffee with gum-water, adding powdered soapstone, and various coloring materials, and placing it in hot revolving iron cylinders, the beans rub against one another, until they acquire the desired color and polish. The coffee brokers assert that more than half the retail grocers sell cheap coffee that has been colored to imitate Java. There are large establishments for coloring coffee near New York, but they claim that their processes are harmless. They however do admit that there are some wicked men in the same business in Holland, and it may have been their coffees that were examined by the Board of Health.

HOW TO DETECT COLORED COFFEE.

First-class retail grocers can procure their stock from importers, and they are in no danger of being served with the colored stuff; but it is different with the average dealers all over the country. Soaking the suspected coffee-grains in water, frequently stirring, or shaking them if in a bottle, then carefully drying them and comparing them with a sample not so treated, will show by a difference in color if they have been tampered with. Nearly all the coloring materials are insoluble in water, and if the water in which the sample of coffee has been soaked is allowed to stand in a wine glass, the coloring matter will settle as a fine powder at the bottom.

New Farm Implements and Appliances.

Print Butter.—There is an end to oleomargarine in this State, thanks to the Legislature and the Governor, who have enacted a bill forbidding the manufacture of the article. Now our advice to our farmer friends is to make the best butter, put it up in

neat packages with their own particular stamp, plainly impressed on each package or lump. One has but to go about New York, to see what prices butter stamped "Houghton" or "Echo" Farm commands. It is in the power of nearly all butter manufacturers, to have a brand and a reputation of their own. Perhaps the best butter stamp is the one manufactured by A. H. Reid, of Philadelphia, Penn.

A Boiler for Steep Grades.—One of the greatest objections to traction engines has been the danger of explosion while running up or down steep grades. The "Ajax" Traction Engine, manufactured by A. B. Farquhar, York, Pa., overcomes this difficulty in a manner shown in the engraving below. A plate of sheet iron is placed over the front end of the boiler tubes, and extends backward and upward. The position of the water, when the engine is descending a grade is seen in the sectional cut. This engine is easily guided

by a patented arrangement, in which the steam does all the hard work.

American Rubber Paint, for several years advertised in our columns, has received general

commendation from our readers. Because we have received only commendation and no complaints, we urge our readers to send to the manufacturer, Edmund Blunt, 115 Maiden Lane, New York, for samples and full descriptions.

About Threshing Machines.—There are some trials of agricultural implements that amount to very little, as the apparent superiority of many machines depends more upon the skill of the operator, or the use of horses accustomed to the work, than to any excellence of the machine itself. With a thresher the case is different; here it is the structure of the machine that allows more or less work to be done with the same power. On this account, the victories won at the various trials by the Fearless Thresher, made by Minard Harder, Cobleskill, N. Y., may be accepted as evidence of its superiority, which is further confirmed by the many individuals who have them in use.

The Carpenter's Steel Square and its Uses.—Few mechanics who have used the square all their lives, are aware of how much may be done with it, or to the extent to which it may take the place of more expensive instruments. The author, Fred. T. Hodgson, has brought together in the present work, the various rules and formulas for laying out, by the use of the square, the various angles, bevels, etc., that builders often have need to construct, and to form octagons, polygons, to lay out stairs, and describe circles and ellipses by its aid. The fact that the present new and enlarged edition was called for within two years from the time of the original publication, shows that the work was appreciated by the mechanics of the country, for whose benefit it was intended; they will find the present edition greatly enlarged and even still more valuable. Price, \$1.00, post-paid.

Quinby's New Bee-Keeping.—A Complete Guide to Successful Bee Culture, by L. C. Root, Apiarian, New York. The Orange Judd Company. The late A. M. Quinby was long regarded as the highest authority in all matters relating to the apiary. While exceedingly cautious with regard to new methods and appliances, he was progressive, and ready to accept whatever was found to be a real improvement, but a sturdy foe to every form of all pretence, charlatanism, and useless patents. His advice was eagerly sought at various Bee-keeper's Conventions, and his work was for many years the standard authority. So averse was he to all secrecy in the methods of the Apiary, that he called his work, when first published: "The Mysteries of Bee-keeping Explained," though this title was modified in after editions to "Quinby's New Bee-keeping." After the death of Mr. Quinby, the work was re-written by his business associate and son-in-law, Mr. L. C. Root, who embodied the later improvements of Mr. Quinby, as well as his own, and in successive editions, including the present, has kept the work up to the requirements of progressive apiculture. While the work as it now stands is essentially Mr. Root's, he modestly appears as associate author, and gives prominence to the name of one who did so much to bring bee-keeping to its present prosperous condition. The present edition, which contains added matter and new illustrations, is now in press. Price, post-paid, \$1.50.

Catalogues Acknowledged.

The catalogues which did not come to hand in time for last month, are given below, and with these we discontinue the publication of the lists until fall. We suggest to our friends that they send their autumn catalogues as soon as they are ready.

NURSERYMEN AND FLORISTS.

J. L. DILLON, Bloomsburg, Pa.—A full collection of green-house plants and small fruits, and makes a specialty of roses.

E. M. FULLER, Bismarck, Dakota.—Green-house and other plants, flower and vegetable seeds, etc. This excellent catalogue shows in a striking manner our wonderful westward progress.

T. S. HUBBARD, Fredonia, N. Y.—Grapes and small fruits. An instructive illustrated catalogue.

IMPLEMENTS, MACHINERY, & MISCELLANEOUS.

BAUGH & SONS, No. 20 South Delaware Ave., Phila., Penn.—Phosphates and other fertilizers, formulas for fertilizers, and the chemicals used in compounding them.

BOOMER & BOSCHERT, Syracuse, N. Y., illustrate the various styles of their powerful press for cider, wine, etc. Also the various accessories used with the press.

BROCKNER & EVANS, No. 422 West St., New York City. Wire netting, and various wire and other appliances for poultry houses and yards, dog kennels, pigeon

houses, etc. Also tasteful garden fences, arbors, and other garden structures.

WM. L. BOYER & BRO., Germantown Ave. & Diamond St., Philadelphia.—Union Horse-power Threshers and Cleaners. Farm Grist Mills and other farm machines.

A. B. COHU & CO., No. 197 Water St., New York City.—A very large and finely illustrated catalogue of farm machinery and implements, including those required by planters in tropical countries. The latest improved forms are distinguished by the trade-mark "A. B. C." Contains everything, from a steam-engine to a garden trowel, besides farm and garden seeds.

J. H. JOHNSTON, Great Western Gun Works, Pittsburgh, Pa.—An illustrated list of rifles, shot-guns, revolvers, and a great variety of accessory implements, fishing tackle, etc.

FRANK L. MOORE, Ponghkeepsie, N. Y.—Illustrates and describes the Nectar Fountain for Poultry.

GEO. L. SQUIER, Buffalo, N. Y.—Describes mills, evaporators, and all other machines for working up sorghum in the "Northern Sugar Cane Manual."

FOREIGN CATALOGUES.

JOSEPH MAYO, Drury, Auckland, New Zealand. A descriptive fruit list. A very large share of the apples are of our own varieties, while the pears are nearly all of French origin.

New American Farm Book.

Originally by R. L. ALLEN.

Author of "Diseases of Domestic Animals," and formerly Editor of the *American Agriculturist*.

Revised and Enlarged by LEWIS F. ALLEN.

Author of "American Cattle," Editor of "American Short-horn Herd-Book."

For the young man of rural tastes, but without a training at the plow handles, who asks for a general guide and instructor that shall be to agriculture what the map of the world is to geography, it is the best manual in print. For the working farmer, who in summer mornings and by the winter fireside would refresh his convictions, and reassure his knowledge by old definitions and well considered summaries, it is the most convenient hand-book.—*N.Y. Tribune*.

Cloth, 12mo. PRICE, POST-PAID, \$2.50.

New, Revised, and Enlarged Edition.

SWINE HUSBANDRY. A PRACTICAL MANUAL

FOR THE

Breeding, Rearing, and Management of Swine,

AND THE

Prevention and Treatment of their Diseases.

By F. D. COBURN.

ILLUSTRATED.

A NEW CITY BEAUTIFULLY LOCATED.

Hindsdale City, adjoining beautiful Garden City—the "loveliest village of the plain"—and Creedmoor Rifle Range, N. Y. Several thousand building lots, surrounding Hindsdale depot, \$175 each, selling on monthly payments of \$5 per lot; four lots, \$10 per month. Prices advanced \$5 per lot monthly until present prices are at least doubled. Cottages \$10 monthly for each \$1,000 of cost. Nuisances and shanties prohibited; no malaria, chills, fevers or mosquitoes; climate, soil, drives and surroundings unsurpassed. Building optional with purchaser; fair dealing guaranteed; nothing over-colored. Buy for investment, residence or Summer home. New York will be

THE FUTURE CITY OF THE WORLD.

Property around it is rapidly increasing in value, and must continue to do so. You enter no uncertain venture by investing in Hindsdale. Prices are low compared with all other New York surroundings; increase certain; prospective value greater than any property equivalent. Hindsdale is 13 miles from New York—35 minutes by rail, and 5 minutes additional by Brooklyn Bridge or Ferry; and the commutation averages 10 cents per trip. It is on the main line of the Long Island Railroad, and is the junction for both Garden City and Creedmoor Rifle Range. Improvements proposed, etc., will render Hindsdale an attractive place of abode. Agents wanted of either sex. Circulars, etc., of

THE GREAT AMERICAN TEA COMPANY

GOOD NEWS TO LADIES!

Now's your time to get up Orders for our CELEBRATED TEAS and COFFEES, and secure a beautiful **MOSS ROSE or GOLD-BAND CHINA TEA-SET** (44 pieces), our own importation. One of these beautiful china sets given away to the party sending an order for \$25. This is the greatest inducement ever offered. Send in your orders and enjoy a cup of GOOD TEA or COFFEE, and at the same time procure a HANDSOME CHINA TEA-SET. No humbug. Good Teas, 30c., 35c., and 40c. per lb. Excellent Teas, 50c. and 60c., and very best from 65c. to 90c. We are the oldest and largest Tea Company in the business. The reputation of our house requires no comment. We have just imported some very fine **WHITE GRANITE DINNER SETS**, (115 pieces), which we give away with Tea and Coffee orders of \$40 and upwards. For full particulars, Address **THE GREAT AMERICAN TEA CO.**

P. O. Box 289. 31 and 33 Vesey St., New York.

"Drink fair, betsey, whatever you do."—*Martin Chuzzlewit.*

TEA CLUB ORDERS.

We have made a specialty for six years of giving away as Premiums, to those who get up clubs for our goods, **Dinner and Tea Sets, Gold Band Sets, Silverware, etc.** Teas of all kinds, from 30 to 75 cents per pound. We do a very large Tea and Coffee business, besides sending out from 60 to 90 CLUB ORDERS each day. **SILVER-PLATED CASTERS** as Premiums with \$5, \$7 and \$10 orders. **WHITE TEA SETS** with \$10 orders. **DECORATED TEA SETS** with \$15. **GOLD BAND or MOSS ROSE SETS** of 44 pieces, or **DINNER SETS** of 106 pieces with \$20 orders, and a Host of other Premiums. Send us postal and mention this paper, and we will send you full Price and Premium List. Freight charges average 75 cents per 100 lbs. to points West.

GREAT LONDON TEA CO. 301 Washington Street, Boston, Mass.

GIVEN AWAY

Ladies canvassing for Tea will do well to send for our Premium List. We have premiums for orders from \$5 to \$50, including Gold Band Tea Sets, Waltham Watches, etc. We send thousands of these orders every year, and have yet to hear of any dissatisfaction from those receiving them. If any lady reader of this paper wishes for a beautiful Gold Band Tea Set, they will find it to their advantage to send us a postal for further information.

JULY DAYS.

The full ripe grain is bending
In waves of golden light;
The new-mown hay is sending
Its sweets upon the night;
The breeze is softly sighing,
To cool the parched flowers;
The rain, to see them dying,
Weeps forth its gentle showers.

THOMAS J. OUSELEY.

After having made a world-wide reputation as the editor of "The Genesee Farmer," Mr. Joseph Harris, for twelve years, without intermission, "Walked and Talked" with the subscribers of the *American Agriculturist*, thereby instructing and entertaining a vast army of readers. After an interval of eight years, Mr. Harris again resumes editorial relations with this journal. Many of his old readers have passed away; but probably there are fully one hundred thousand to warmly greet him on his return. A life-long student of agriculture, educated at Rothamsted, with Lawes & Gilbert, he resumes his labors here, with the additional rich experience and study of these eight years. Dr. George Thurber, who for nearly a quarter of a century has stood at the head of our editorial force, Dr. Byron D. Halsted, who for six years has ably seconded Dr. Thurber, Andrew S. Fuller, and all the other able associate writers, who have carried the *American Agriculturist* to its present success, welcome Mr. Harris back to his former field of labor.

Writers for the July American Agriculturist.

Dr. George Thurber, N. J.	R. G. Newton, Dak.
Joseph Harris, N. Y.	Rev. William Clift, Conn.
Dr. B. D. Halsted, N. J.	M. J. G. Hammack, Ill.
Col. M. C. Weld, N. J.	J. M. Stahl, Mo.
Andrew S. Fuller, N. J.	Alfred Trumble, N. Y.
Prof. S. R. Thompson, Neb.	B. W. Jones, Ga.
Dr. D. D. Slade, Mass.	W. D. Boynton, Wis.
Henry A. Haigh, Mich.	I. E. Charles, Ind.
Dr. Charles W. Dabney, N. C.	E. E. Rexford, Wis.
R. L. Harrison, R. I.	James Richardson, N. Y.
L. D. Snook, Fla.	Mrs. E. S. Welsh, N. Y.
W. Z. Hutchinson, Mich.	Ethel Stone, N. J.
Theodore Goodrich, Ill.	Nellie Burns, N. H.
M. E. Bamford, Cal.	Amelia H. Botsford, N. Y.
L. C. Root, N. Y.	Agnes (Carr) Sage, N. Y.
John Bartlett, Ont.	David W. Judd, N. Y.

As in the past, so in the future, we shall make the illustrations a great feature of the *American Agriculturist*, and thereby, as for twenty years, aim to both instruct and please hundreds of thousands of homes. Will all contributors, as far as may be, accompany their articles with plain sketches and designs, which so much aid the reader in understanding the subjects treated.

The *American Agriculturist's* Microscopes, manufactured exclusively for us, and obtained through no other source, are proving a grand success (see another page). At this period of the year they are valuable for the examination of flowers and plants, and the various injurious insects that prey upon the grains, fruits, and flowers. Every farmer, every gardener, everybody should have one of these beautiful new microscopes. Elsewhere read the "free terms" on which it can be procured.

All subscribers will confer a great favor upon us, by immediately forwarding any Autograph letters, any documents with the ear-marks, or any Appeals to them to subscribe to any other journal—so worded as to plainly indicate that their names may have been dishonorably or dishonestly secured from the *American Agriculturist* office.

See page 312 for matters of importance to readers of the *American Agriculturist*.

Advance.
Keep a record.
Tar sheep's noses.
Take your holiday.
Work for success.
Weed out poor hens.
Drink little ice-water.
Observe rigid cleanliness.
Insure the farm buildings.
Hot weather favors vermin.
A pig loves a run in the clover.
Late cabbages require rich soil.
Buckwheat mellowed cloddy lands.
Give a frequent change of pasture.
Unclean stables breed bad disorders.
A hundred-day pig may be very profitable.
Pure drinking water is of the first value.
Muzzle the horse when the corn gets large.
Harvest the wheat in the "doughy" state.
Young stock need a separate feeding-place.
Timber cut in mid-summer is most durable.
Improve the live stock through better males.
Protect the work horses from flies with sheets.
Ripe, woody, late cut grass does not make good hay.
Sheep need shade and shelter, as well as food and water.
Top-dress newly mown meadows with fine manure.
Cultivating the corn prepares the soil for future crops.
A clover sod turned under is a heavy coat of manure.
Poor layers and bad mothers should go to the block.
Salt the stock once a week; not necessarily on Sunday.
Dry earth makes good bedding for cattle in mid-summer.
Cut millet or Hungarian grass before the seed gets ripe.
Give work horses frequent and small drinks of cool, pure water.
Flat turnips sown now, will yield excellent food for sheep in late autumn.
Sow buckwheat for second crop, or to fill out where another has failed.
Place a wet cloth in the crown of the straw hat; it may prevent sun-stroke.
Superphosphate is a most acceptable fertilizer for ruta bagas sown this month.
Manure begins to draw interest as soon as spread, payable at the next harvest.
Select a portion of the corn-field for seed, and give it extra attention. Breed up the corn.
Repeated sowings of fodder-corn make a continuous supply of green feed at the close of the growing season.
The root crop has superseded the summer fallow in the rotation, and the use of the land is no longer lost for a whole year.
Horses as well as boys enjoy an evening bath. They are profited by it if lasting only a few minutes, and they are subsequently rubbed dry.

Orchard and Fruit Garden.

During the present month and the next, the orchardist and gardener finds work less pressing than at any other time, and he is wise if he takes a vacation. A week at the sea-side, or on the shore of an inland lake or river, will do wonders for recruiting one for the work of the autumn months. Go among the fruit growers and gardeners, see what others are doing, and how they do it. Such visits are useful to both giver and receiver.... Insects demand attention every month. The Apple-worm is noted elsewhere. The Apple-borer and the Peach-borer must be looked for; if their saw-dust is found, or there is a depression in the bark of young trees, cut for and probe out the worm.... The Currant and Gooseberry bushes, if attacked by the worm, must have powdered White Hellebore, a tablespoonful thoroughly stirred in a pailful of water, and freely showered to wet the leaves.... The beetles and large caterpillars upon the grape-vines may be picked off by hand.... If a Strawberry plant is seen to wilt, search at its root for the White Grub, and kill it before it can go to another plant.... The shiny, green Slug upon the leaves of pear and cherry trees, may be destroyed by dusting them with air-slaked lime, or wood ashes.... Blight is often destructive to the pear. All that can be done is to remove the blighted portion, whether a small branch or the whole tree, and burn it.... Budding may be done as soon as buds are mature, and the stocks are ready. The cherry is usually the first, followed by the plum and pear.... Summer Layer the Grape.—Shoots of this season that are sufficiently hardened, may be bent down and have a portion buried in the soil; roots will soon form upon it.... Wind Falls.—If pigs are not pastured in the orchard, the fallen fruit should be picked up and fed to them.

Kitchen and Market Garden.

Success in keeping down weeds, depends upon attacking them while they are small. A sharp rake is most effective if applied early. The use of the cultivator must be supplemented by hand weeding in the rows.... Asparagus tops make a dense shade, and keep down small weeds; if any large ones appear, pull them.... Sowing seeds for Succession Crops, and setting out plants for late ones, will be the chief work this month. Sow Early Beets (see p. 234). Of Bush Beans, the Refugee is preferred for late planting. Sweet Corn, of early quick growing varieties, may be planted for table and for drying.... Sage, Thyme and other sweet herbs, may be set out, also late Cabbages, Cauliflower, etc.... Celery is to be set out from the seed bed. If ground can be used from which a heavily manured early crop has been removed, all the better; otherwise the soil must be well manured. Mark out the rows, three, or better, four feet apart, setting the plants six inches apart in the rows, taking care to set them no deeper than they stood before. Press the soil gently and firmly to the roots with the feet, and if it be dry, give an abundant watering. Afterwards keep the celery clear of weeds.... Ruta Bagas and other turnips, may be sown as indicated elsewhere.... When vines of Lima Beans extend beyond the tops of the poles, nip off their ends.... Tomato vines must be kept tied up to the trellis; remove all badly shaped fruit; hand-pick and kill the great green worm.... Egg-plants.—Keep the potato bug from them, and place straw under the fruit to keep it from the ground.... Sweet Potato vines should not be allowed to take root at the joints; move them at each hoeing.

Flower Garden and Lawn.

When the grass is growing rapidly, it may be mown frequently; on the other hand, if a drouth checks the growth, the grass may be injured by using the mower too often. Large weeds should not be allowed to get established; take up docks, plantains, etc., as soon as discovered. An old thin chisel fixed to a handle, makes an excellent "spud" to aid in uprooting large weeds. Beds planted in Ribbon Style, need care, and if plants in the different lines run into one another, they must

be cut away to keep the outline distinct.... Perennial Plants, except in rare cases where seeds are wanted, should have the flower clusters cut away as soon as they begin to fade.... Dahlias, Gladioluses, Tuberoses, etc., will need stakes; let them be inconspicuous, and placed out of sight.... Annuals of all kinds will keep in bloom much longer if not allowed to ripen their seeds.

Award of Prizes.

The following persons were the successful competitors for the prizes offered in February for essays upon Feeding and Care of Farm Animals: First prize (\$50), to "A Western Farmer"—Mr. Fred. Grundy, Morrisonville, Ill. Second prize (\$40), to "Stock-breeder"—George Ashbridge, West White-land, Pa. Third prize (\$30), to "Zero"—F. A. Deekens, Federalsburg, Md. We will favor our readers with a portion, at least, of the first prize essay in the next issue of the *American Agriculturist*. We remind all writers that they have until September 1st to compete for the prizes for short juvenile stories, offered in June last.

Cabbages as a Farm Crop.

JOSEPH HARRIS.

Last year millions of cabbages were imported into this country from Europe; and such was the case in 1882. They are used largely for Sauerkraut. In foggy weather cabbages are liable to heat or mould on the steamers, and the expense of getting them here is very great. The price in the New York Market ranged from ten to fifteen cents per head. Prices in the inland cities and villages were still higher. A farmer can well afford to raise cabbages for three cents a head. And the crop has this great advantage—if it cannot be sold it may be fed out on the farm to cows, sheep, or pigs.

For late autumn or winter use, cabbages can be planted from the last of June, until the middle of August. The large varieties, such as the Large Late Drumhead, Premium Flat Dutch, and Short-stem Drumhead, should be planted as early as convenient in July. If it is necessary to plant late in the season, select the earlier varieties. For this purpose there is nothing better than the Early Winningstadt.

As a farm crop, cabbages should be planted in rows, three feet apart, or sufficiently wide apart to admit the use of a horse-hoe, or cultivator. Low swampy land that is too wet for corn, can often be planted to cabbages with great advantage in July. If the land is smooth and clean, the plants may be set in rows two and a half feet apart, but if rough, and not in fine condition, make the spaces wider.

It is very little work to set out an acre of cabbages. Mark out the land as you would for planting corn, and instead of dropping corn, set out a cabbage plant. The better way is to mark the land both ways, and let a boy drop the plants where the rows cross. If the land is in good order, a man and boy should set out at least an acre a day. If you have not cabbage plants of your own, they can be purchased at very low prices—say from one dollar to two dollars per thousand, according to the quantity ordered. You should get more plants than you need, in order to have enough to replace any that may fail to grow. If you plant three feet apart each way, there should be four thousand eight hundred and forty plants on an acre. If three feet by two and a half feet, five thousand eight hundred and nine per acre; if three feet by two feet, seven thousand two hundred and sixty plants per acre; if two and a half feet by two and a half feet, which will answer for Winningstadt cabbages, there will be six thousand nine hundred and seventy plants per acre. When the plants get fairly started, nothing more is required, except to use the cultivator freely between the rows, and to dress out the weeds around the plants with a hoe. Thorough cultivation is the essential point.

If you are afraid of the green worm, set out five acres instead of one acre. There will be about as many worms on the small patch as on the large one.

The Apple-Worm—The Codling-Moth.

From their letters of inquiry, it is evident that some of our correspondents think that the Apple-worm and the Codling-moth are different insects. It will simplify matters if they understand that the "worm" is the grub or larval state of the moth. This pest has been so general, and has so rapidly increased, that a few years ago it seemed to threaten to make orchard culture unprofitable in many localities. Recently, however, remedies have been devised which should encourage the fruit-grower to hope that he may successfully combat this, his most destructive enemy, and if their application can be made general, promise a better future for the orchardist. The life history of the insect may be briefly stated thus: In spring, about the time the fruit has "set," a little gray moth leaves the chrysalis in which it has been dormant all winter. As this moth flies only at night, it is rarely noticed, making its way to the young fruit, where it deposits a single egg in the calyx or blossom end of each.

The egg hatches in a few days, and the little worm eats its way into the young apple, and attains its full growth in about two weeks. It then leaves the apple by a hole it makes in the side and descends the tree. Finding a crevice, or a sheltering scale of bark, the worm conceals itself there, and spins a cocoon. In two or three weeks, the moths emerge from these cocoons, and are ready to go through the same performance again, laying their eggs and stocking the apples with a second supply of worms, which complete their growth, descend the tree, find a hiding place as before, and make their cocoons. Instead of leaving their cocoons in two or three weeks, as did the first brood, the moths do not issue from them until the following spring, in proper time to lay their eggs upon the recently set fruit. Of the fruit containing this second brood, a large share of it falls to the ground; the worms, when full grown, leave the fallen fruit, and if they find no shelter at hand, affording a hiding place, crawl back to the tree, ascend its trunk, and finding a secure place, make their cocoons. The methods of destroying the insect depend upon a knowledge of the facts here briefly stated. A most important addition recently made to the other modes of warfare, depends upon the fact that the apple, when young, is erect, with its calyx or blossom end upward. As the fruit grows and becomes heavy, it turns downward. Acting upon this fact, and the other, that the young worms enter the apple from the blossom-end, some Western orchardists have applied Paris Green, which poisons the worm, as it attempts to eat its way to the interior of the fruit. The tree is so abundantly showered with water in which the poison has been stirred, that a little will fall into each upturned blossom-end of the young apples. Very little Paris Green is required, a tablespoonful thoroughly distributed through (for it does not dissolve), a barrel of water is sufficient. The barrel is placed upon a wagon of some kind, and its contents showered into the trees by means of a force pump. The least particle of the poison kills the worm. So little is applied that no harm could result from the use of the poison, did not the rains completely remove all traces of it. The season for poisoning is past, but there are other measures that may yet be taken. If the trunks of the trees were not scraped in early spring, let it be done at once; then apply a bandage of some kind around the trunk of each tree. Woollen fabric is best, old carpet answers well, but any rags will answer. The bands may be about six inches wide, long enough to go around the tree and lap slightly and be fastened by a single tack at the lapped portion, being careful to not drive it in so far that it cannot be readily removed. The worms will seek the shelter of these bands, and spin their cocoons. The bands are removed every ten days, and the worms or their cocoons crushed. They may be killed by hand or by passing the cloth through a clothes-wringer. The branches should be shaken, to cause wormy apples to fall, and these, and all those which drop spontaneously, should be picked up and fed to pigs, or the worms they contain otherwise destroyed.

A Southern Well-House and Bath-Room.

Few southern people in moderate circumstances would dispense with their bath-room. Instead of adjoining the sleeping room, as at the North, the bath-room is usually in a separate building, located near a spring or well. A very desirable bath-house and well-room combined, is shown in the engraving. The apartment containing the pump may be completely surrounded with lattice work, and when practicable, quick-growing vines should be trained over the lattice, giving the whole a cool, refreshing appearance. Instead of windows to

A WELL-HOUSE AND BATH-ROOM COMBINED.

light the bath-room, there may be lattice-work from beneath the eaves, down to five and a half feet from the ground. At the South the water is seldom warmed, and is usually pumped directly into the bath tub. The outlet pipe should discharge the waste water several rods from the well. The building shown in the engraving is ten by fifteen feet, a little more than half being used for the bath-room.

The Grapevine in Summer.

There is no time, from the first pushing of the shoots, until the leaves are ready to fall, but destructive insects of some kind attack the grapevine. Fortunately, the later insects are mainly large caterpillars or beetles, and one who is frequently among his vines, can destroy them before they can do much injury. The great pest in the hot months of July and August is mildew, and the vine grower should be constantly on the look out for it. Some varieties of the grape are much more subject to its attacks than others, and these vines should be watched for the first appearance of the scourge. Whitish or grayish spots or blotches on the under surface of the leaves, are mildew, and the remedy, a thorough dusting with sulphur, should be applied at once. Sulphur bellows are now kept in the seed and implement stores. Before using, the sulphur should be run through a sieve, in order to remove all lumps. Too large a quantity should not be placed in the bellows at one time, and in using it, the bellows should be so worked as to deliver a cloud of fine dust. Choose a still, hot day, and endeavor to have the under surface of the leaves as thoroughly dusted as the upper. A second dusting of sulphur may be made in about a week after the first, and it should be applied all through the season if mildew appears. Not only in early spring, but later in the season, strong, vigorous shoots will appear upon the main stem of the vine. These start at no particular place, and grow with great rapidity. Novices in grape culture are puzzled as to the proper treatment of these shoots. A shoot from a regular bud, if not needed, is broken away, and the same should be done with these chance shoots. Unless a cane is needed just where such a shoot appears, break it off. The laterals puzzle many, but their treatment is very simple. As a shoot grows, there will be found two buds at the axil of each leaf—the part where the leaf joins the stem. Later, one of these buds will start into

growth—this shoot is called a lateral. We wish to keep one bud perfectly dormant, for next year's fruiting. If the shoot from the bud that has started were pulled out, the other one would start into growth, and there would be no fruit from it next year. The proper treatment of the laterals is, to pluck them back to one leaf, as often as they push.

Cuttings of Unripe Wood.

The experience of amateur gardeners in raising plants from cuttings, is, as a rule, confined to the currant and the grape. Cuttings from the ripened wood of currants of all kinds, take root very readily. The cuttings made from the prunings of most, but not all, varieties of the grape, will take root and form new plants. Amateur gardeners who would like to propagate their ornamental shrubs, find if they take cuttings, as they would of the currant and grape, from the ripe wood, they rarely succeed. Shrubs that refuse to be propagated from pieces of the mature stems, will usually succeed if cuttings are made of green, or just hardening stems. Cuttings of this kind have leaves, from which evaporation

goes on rapidly; if planted in the open air, they will be very apt to fail. To succeed, it is necessary to provide a moist atmosphere, or as the old gardeners would say, "keep them close." A hand-light or bell-glass, placed over such cuttings, will provide a moist atmosphere, and insure success. But we write for those who are not supposed to have all garden conveniences at hand, and such, in the absence of hand-lights and bell-glasses, can provide a useful substitute from an ordinary box. Knock off both top and bottom, leaving a mere frame, and tack over it, in place of the top, a piece of cotton cloth. If the cuttings are planted in sandy soil, and covered with a frame of this kind, undue evaporation will be prevented, and a large share will take root. The amateur may try for his shrubs what we have frequently described for soft-wooded plants, as the "saucer method." A deep plate or saucer is filled with clean, sharp sand, the cuttings, an inch or two long, are set close together in this, and the sand is kept constantly wet, as wet as mud. Here the abundant water supplies the loss by evaporation from the leaves, and the dish and its contents may be exposed to full sunlight. Cuttings for this method should be very young and tender. If the sand is kept constantly wet, a surprising number of cuttings will take root. As soon as roots appear, the young plants should be potted in good soil. This method of striking cuttings affords to amateurs an interesting field for experiment. Some shrubs may be propagated by placing the lower portions of cuttings of their stems in a bottle of water and exposing them to the light. This is a very common method with the Oleander, but cuttings of other shrubs may be tried in the same way. As soon as roots are formed on the cuttings, they should be potted in somewhat sandy soil.

When and How to Harvest Wheat.

Mr. W. H. Burtis, The Glades, Ga., and others, ask us for information on the proper time to cut wheat. It is the experience of the best wheat growers in our own and other countries, that a superior quality of grain is obtained by harvesting the crop when the berry is in the soft or "doughy" state; that is, when the grain may be readily crushed between the thumb and finger. It is claimed that more bushels per acre, and a greater amount of flour of a better quality per bushel is thus obtained.

Starch and gluten are the most valuable constituents of wheat, and the quantity of these is diminished by over ripening, while the per cent of woody fibre is increased. Every farmer can readily make a practical test of this question, by cutting a part of his wheat earlier than the rest, threshing, weighing, and grinding the grain separately. The method of harvesting the grain has much to do with its quality. One of the greatest sources of loss arises from the careless and hurried manner of shocking the bundles. If the shock becomes thoroughly wet, as it is sure to be in "catching" weather, if not properly made and protected, the grain begins to grow, and only an inferior bread can be made from it. There are several methods of arranging bundles in the shock; they may be set in pairs, forming a row of ten or twenty, or in round shocks. The long stooks expose a broad surface to the winds, and may be blown down, when the well-set round shock would stand the storm. The latter form also more readily admits of "capping." A secure small shock may be made of three pairs of bundles set closely and firmly, with two more bundles upon each side of the double row. The heads of the bundles are brought up together, and a cap-sheaf placed over all. This cap is an ordinary bundle, with the band placed six or eight inches from the butt, and the top bent out into the shape of a funnel. A larger round stook consists of four pairs of bundles, with three sheaves on each side, making fourteen, upon which two cap-sheaves are placed, each made as above described, with one side of the funnel left open where the two sheaves join on the shocks. A boy may aid in bringing the sheaves into piles, but it is no economy to employ him to shock them. It is a common practice to cut and bind until night-fall, and afterwards set up the sheaves in the quickest way possible. Of all harvest work, the shocking of grain should be done with the greatest care; otherwise a hard storm may convert the poorly made shocks into piles of decaying straw and growing and nearly useless grain.

Burning Down Trees.

In the Southern States, especially Florida, the pine trees are usually burned down when clearing the land. This practice could often be advantageously followed at the North. Figure 1 shows the common plan. A hole about twenty inches deep and two and a half feet square is dug on the leaning side of the tree, so that when it

Fig. 1.

Fig. 2.

falls the opposite roots if any remain unburned will be pulled out. The lower part of the trunk thus exposed is struck a few times with the axe, and left a short time for the pitch to exude. A fire is kindled in the hole as shown in figure 1. Trees ten inches in diameter are burned off and the roots burned out below the plow line in twenty to thirty hours. A more expeditious way is given in figure 2. A hole is dug as before described, also removing eight or ten inches of the earth from the opposite side. With an inch and a half or two inch auger, a hole is bored through the tree at an angle of forty-five degrees, as shown above. For this purpose a ship auger is used, or a long shank may be welded to a common one. The hole thus bored acts as a chimney, and soon not only the side of tree is on fire, but the chimney part as well. The tree is burned down in less than one-third of the time required by the old method. A strong man can bore nearly fifty of these holes in a day. Stumps are removed in the same manner, and if dry, in a considerably shorter time than trees.

Bee Notes for July.

W. Z. HUTCHINSON.

MAKING HONEY VINEGAR.—The "cappings" shaved off in the preparation of honey for extracting, are always allowed to drain. But even when thoroughly drained, considerable honey still adheres to them, and it is an excellent plan to have a keg or a barrel of water in which to wash them, and to allow the water to ferment and become vinegar. Water which has been used to rinse out any utensil that has contained honey, can be thrown into the barrel. The seum that arises upon the surface of the sweetened water should be skimmed off.

MAKING BEESWAX.—The "cappings" which accumulate in the extraction of honey, and all odds and ends of comb, should be carefully saved, but, in warm weather it is well to render them into wax as soon as possible; otherwise they are liable to become infested with the bee moth's larvæ. What is called a Swiss wax extractor, is a convenient utensil for rendering wax. It is simply a "basket" of perforated zinc, inside a "steamer" which is set over a kettle of boiling water. The refuse comb is placed in the basket, and the steam rises and melts the wax, which is caught by a false bottom in the steamer, and runs out through a spout in the side. When there is not much wax to render, the cappings of combs can be put into a tin sieve, the sieve covered, and then set over a pan of boiling water. The steam will melt the wax, which will run down and rest upon the water in the pan. The pan and its contents can be set aside until cold, when the wax will be found formed into a cake. Another method is to put the combs into a cloth sack, and the latter into a wash-boiler—the sack being held at the bottom of the boiler by means of a stick, the upper end of which presses against another stick, lying across the top of the boiler, and tied to its handles. When the wax is melted, the boiler is set aside until the wax is cool enough to be removed. Wax can be cleaned from utensils, by using a cloth saturated with kerosene oil.

FUEL FOR SMOKERS.—Many substances have been recommended as fuel for smokers, but nothing has given the writer more satisfaction, than what is sometimes called "punk," a peculiar kind of dry rot. That from the maple tree is best.

ANTS.—To circumvent the little ants, that sometimes prove themselves such nuisances by getting into honey, place it upon a table or platform, the supports of which rest in dishes partly filled with kerosene oil. A muslin cover with a rubber cord in a hem around its edge, will exclude dust and insects from a vessel holding honey.

A BEE STING REMEDY.—Veteran bee-keepers rarely trouble themselves with bee sting remedies, but amateurs, and those in whom the flesh swells when stung near the eyes, often wish for something that will reduce the swelling and pain. The best remedy known to the writer is a tincture of Plantain, made by pouring alcohol over the freshly gathered leaves, and allowing it to remain until it turns black, when it is poured off and bottled. If this remedy is applied immediately after the wound is given, the swelling and pain will be scarcely perceptible. If the person is severely stung, a few drops of the tincture can be taken internally.

RIPENING HONEY.—When first gathered, honey is generally quite thin and watery, so that it can readily be shaken from the combs, but the heat of the hive, aided by the manipulations of the bees, soon reduces it to the proper consistency, when the bees seal it over. It has been asserted that larger quantities of honey can be obtained, if it is extracted when first gathered, but, when taken in this "green" condition, it must be ripened by artificial means.

Otherwise it ferments. It will rarely do so, if nearly ready to seal when extracted, and if allowed to stand in open vessels, the excess of moisture will in time evaporate. Mr. Pettit, a Canadian, has the following method of ripening honey. During a bountiful yield, he extracts as often as once in three days, and when a barrel is full of honey, it is raised by means of ropes and pulleys, to the upper part of the honey room. The faucet to the barrel is slightly opened, and a small stream of honey allowed to trickle upon the upper edge of a sheet of tin, having a slight inclination. From the lower edge of the tin, the honey drips upon the upper edge of another sheet, placed under the first, but inclined in the opposite direction. From the lower edge of the second sheet of tin, the honey drips upon the upper edge of a third sheet, from the third to the fourth, and in this manner it continues to flow from sheet to sheet, until it passes over about thirty sheets, when it runs into a large vat. To prevent the honey from running off at the sides of the sheets, their edges are slightly turned up. Mr. Pettit has never found it necessary to run the honey through the evaporator more than once.

HONEY DRYING APPARATUS.

There is some difference of opinion, however, as to whether honey thus artificially ripened, has the fine, aromatic flavor, and smooth, sweet, oily taste, of that thoroughly ripened in the hives. The writer's experience in this matter would lead him to decide the question in the negative.

New Varieties of Honey Bees.

L. C. ROOT, AUTHOR OF "NEW BEE-KEEPING."

Through the efforts of Messrs. D. A. Jones, Frank Benton, and others, who have spent much time and money in this direction, several varieties of bees, new to this country, have been introduced, and their comparative value to some extent tested.

The Cyprians have some marked characteristics. They have been quite thoroughly tested, but do not grow in favor with the majority. They are far too irritable to be agreeable to handle. Some consider them superior honey-gatherers. I have given them quite a thorough trial, and the only point I could find in their favor, was a tendency to breed late in the fall, which is desirable as affording a good force of young bees when going into winter quarters. I have not tested the Syrians. Mr. Benton pronounces them among the very best. The Carniolans are said to possess some very desirable qualities, and a cross between them and the Italians has a good reputation. Much has been said of the Holy Land or Palestine bees, but my own experience does not corroborate all that is claimed for them.

Mr. Julius Hoffman received an importation of Caucasian bees in 1880. He has experimented quite extensively with them, and is of the opinion they are superior in many respects. In fact, I have never heard more desirable points claimed for any one variety than Mr. Hoffman claims for these. He is one of our most practical bee-keepers, and his conclusions should be received with confidence. Much credit is due those who have been so persevering in securing to us these new varieties. The

ultimate results must be of great good, as the future crossing of these strains will no doubt give us one with a combination of very superior traits.

The Cow in Midsummer.

On farms where the dairy is an important part of the husbandry, provision is made by sowing soiling crops, to supplement the diminished pasturage in midsummer. Those who keep only the "family cow," or at most two or three cows, find the flow of milk to decrease, and often without any green crop provided for keeping it up. The territory of those who keep but a single cow, is often restricted to a small pasture and a vegetable garden. The garden should be made to supplement the pasture, and this may be done to some extent by securing for the cow much from the garden that usually goes to waste. Every one who has a garden, tries to have an abundance of green peas. After the vines have yielded their last profitable picking, instead of allowing them to remain upon the ground until that is wanted for another crop, feed the vines to the cow while they are still green and succulent. So with sweet corn. When the last ear is plucked from a stalk or a hill, do not wait until the whole patch or row can be cleared, but pull up the stalks that have been deprived of ears, a few at a time, and feed them while in their best condition. The outer leaves of early cabbages, and the leaves of beets, carrots, and turnips, carefully saved, will make an important item in the succulent food for the cow. If there is a space in the garden, from which an early crop has been removed, and it is not needed for a late garden crop, it should be growing something for the cow. Sweet-corn may be sown thickly in rows for "fodder corn," and afford welcome feed. It is well to have an abundance of cabbage plants of a large late variety, and set them out wherever there is room, and far beyond the needs of the family. An occasional cabbage next winter will be a treat to the cow. Experiments made a dozen years ago with some twenty varieties of the Southern Cow Pea showed, incidentally, that, even at the North, if they did not ripen their seeds, they would give an enormous weight of herbage upon a small area. This pea is highly valued for animals at the South, both fresh and as hay, and seems to be worth trying in Northern localities, as a soiling plant. Where there is room, even a few square yards, it may be well to sow either Hungarian grass, or one of the plants called Millet, for late summer feed for the cow. If the soil is rich, an abundant crop may be cut. Besides summer feed in the garden, if there is room there or elsewhere, it is well to think of Jerusalem Artichokes as a winter treat. It is late now for a large crop, but with the tops, which are highly relished, the tubers, being crisp, succulent and highly nutritious, will be most acceptable as an addition to dry fodder. When one once fairly undertakes to produce the greatest possible amount of cow food from a small area of land, he will be surprised at the results that he obtains, especially those seen in the pail.

Blight in Different Varieties of Pears.

In an orchard of five hundred pear trees, three hundred Louise Bonne de Jersey, and two hundred Bartletts, planted in 1876, the blight had killed, up to last year, forty Bartletts, and about as many of the Louise Bonne. This season four per cent of the latter, and six per cent of Bartletts have been reset. In another orchard of an equal number of trees set in 1882, quite a number were reset last spring, and this year the loss by blight and a few by accident, was of Bartletts twelve per cent, Osband's Summer eight per cent, and of Duchess de Angouleme less than two per cent. Thus it will be seen that the Bartlett is most subject to blight of the four varieties. Indeed the loss among three hundred and fifty Bartletts was nearly as great as in six hundred and fifty trees of the other three kinds.

The Bartlett is a deservedly popular variety with buyers of fruit, and by them is considered a

standard of excellence. Though it commands a ready sale, and is an abundant and regular bearer, yet it is peculiarly subject to blight. Can we afford to plant a pear so universally short lived? A mortality of twelve per cent annually, is a very serious loss, amounting to an entire renewal of an orchard every ninth year. Under the most favorable circumstances, with these figures, not more than four crops could be expected, even if the trees lived the full term of nine years. Would this amount of fruit be a sufficient remuneration for the cost of the tree, its planting and cultivation for the other five years? A much larger number of Bartlett are planted than of any other variety; is the practice to be recommended? A superabundance of one variety will make a glut in any market. Would it not be better to partly substitute Duchess that is subject to a loss of only two per cent? This would be of assistance in time of a glut, and materially decrease death by blight. THEODORE GOODRICH.

Gooseberries.—New Variety.

The English gooseberries, noted for their great size and fine quality, are rarely seen in our markets. They are so subject to mildew that only a few fanciers, mainly Englishmen, endeavor to cultivate them, and by a constant fight with the mildew, manage to secure dearly earned small crops of their favorite fruit. The varieties grown for market are American seedlings. The first of these, the "Houghton," was many years ago raised at Lynn, Mass., and in spite of its small size, its freedom from mildew, and the abundance of its fruit, caused it to be widely cultivated. Numerous seedlings were raised from the "Houghton;" several with larger fruit than the original, are on that account preferable to it. The best of these originated with Charles Downing, and is known by his name. Probably nine-tenths of all the gooseberries produced for market are gathered and sold while green, and are used for cooking. When ripe they are not large enough or of sufficiently good quality to be a satisfactory desert fruit. A good gooseberry is so desirable, it is not surprising that fruit-growers should test the new varieties which are produced abroad, in the hope of finding one that can be

grower, and immense yielder, and as showing no signs of mildew. The size of the fruit is shown in the engraving; the color is dark red, skin somewhat hairy, and the fruit is said to be of pleasant, rich flavor. We shall look upon the future of this berry with interest, and hope it may prove to be the fruit so long desired by the lovers of gooseberries, in all portions of the United States.

California Lemons and Limes.

Among the institutions peculiar to Southern California are the Citrus Fairs, held annually in different cities. At these fairs, in addition to the many varieties of oranges with which the halls are crowded, there are exhibited a great quantity of lemons and limes. At a recent Citrus Fair, held near San Diego, twenty-six varieties of lemons were shown, with sixteen of limes. Many of the lemon-clusters suspended from the ceiling were very fine, as were also the pyramids and trays of this fruit exhibited on the tables. The "Eureka" lemon took the prize at this Fair for the best budded fruit.—About one hundred and forty thousand lemon trees are now growing in the orchards of California. Around San Francisco Bay the lemon is often planted in the open air, where it sometimes grows to be seven or eight feet high, and bear fruit; but the southern portion of the State is better adapted to it. In Los Angeles County, alone, the number of lemon trees, according to the assessment roll of 1883, was fifty thousand, five hundred and sixty-five. At Riverside, in San Bernadino County, there are twenty thousand trees, and the crop of 1881-82 amounted to three thousand eight hundred boxes of lemons, and five thousand of limes. Lemons and limes are also cultivated in Santa Clara, Stanislaus, Fresno, San Luis Obispo, Ventura, and San Diego counties. The Steily and Malaga lemons are the varieties most cultivated, although the Chinese is very prolific. This lemon is very hardy, but never becomes a tree of more than ten feet high. Lemons do not require more than a third as much water as oranges, and for this reason the two are rarely planted together. Many farmers surround their lemon orchards with hedges of limes as wind-breaks. As the limes seldom grow to be more than bushes of from four to about ten feet high, they answer the purpose of a hedge.

In many parts of Southern California limes are so common, that every year great quantities of the fruit drop to the ground and are allowed to decay. Among those who have regular lime plantations, from one to two hundred bushes occupy an acre. There are two crops yearly for the limes, one in January and the other in June. Lemons are generally more profitable than oranges. When in good bearing, a lemon tree will yield about fifteen hundred lemons per season. The cost of gather-

ing the fruit and shipping it from the southern part of California to San Francisco, is about five dollars per thousand. About the same amount must be paid for water per acre. The general estimate is, that the ordinary yearly profit of an acre of lemon trees in good bearing amounts to one thousand dollars. The chief objection to the lemon as a fruit tree is its slowness in coming into good bearing. For the first ten or a dozen years, the tree does not bear heavily, but after that the profit is sure. One fifteen-year-old tree in Los Angeles, a few years ago bore two thousand lemons, which sold in San Francisco for sixty dollars, and at the recent Citrus Fair, one of the exhibitors

A NEW BLACKBERRY—"EARLY HARVEST."

stated, that he had sold this season from one tree, within three months, fourteen hundred lemons, and still the tree was well loaded with fine fruit.

The lemon is as easily propagated from seed, cuttings, or suckers, as the orange. About eighty trees are planted on an acre. A lemon orchard does not present so beautiful an appearance as one of orange trees, for the foliage is less luxuriant and the branches are irregular. The lemon blooms here about the first of March or April, the first crop being then on the tree. The second crop comes in the summer, and the third in the autumn.

New Blackberries.—Early Harvest.

There appears to be "a boom" among blackberries, more new varieties having come forward during the past two years than during any corresponding period. Cultivators appear to be working in the direction of earliness, and to "Wilson's Early" and "Early Cluster," they add the "Early Harvest." Is great earliness desirable in a blackberry? It is of importance to the fruit-grower to have the fruits follow one another in regular succession, and blackberries are not wanted until the raspberry crop is out of the way. It is claimed for the "Early Harvest" that it is the earliest of blackberries, being ten days in advance of the "Early Wilson." It strikes us that while extreme earliness is not desirable, there are directions in which the blackberry may still be improved. As to quality, if there is a berry superior to a well ripened "Kittatinny," we have not seen it. What is now especially needed is, a blackberry that will be ripe when it is black, and which, after being picked will retain its brilliant jet-black color, without becoming dull and brownish after a few hours' exposure. It is said that the "Early Harvest" originated in Illinois, and has been cultivated to some extent for the Chicago and other markets. The few who have tested it at the East, report in similar terms with the western growers, viz: that it is a very hardy and prolific variety; the fruit ships well, and it is thus far the earliest of all the blackberries. As the "Early Harvest" has been largely planted for market at the East, we shall soon learn its value as a market fruit there.

A NEW GOOSEBERRY—"INDUSTRY."

grown in our climate. A new foreign variety, the "Industry," has been offered this year by a nursery, the proprietors of which are well known pomologists, and when they say that they think "it is destined to revolutionize gooseberry culture in this country," we are sure that they have good grounds for the belief. The bush is described as a vigorous

ed to decay. Among those who have regular lime plantations, from one to two hundred bushes occupy an acre. There are two crops yearly for the limes, one in January and the other in June. Lemons are generally more profitable than oranges. When in good bearing, a lemon tree will yield about fifteen hundred lemons per season. The cost of gather-

A Threshing Flail.

The engraving shows a simple flail, which works easily, and wears much longer than the wooden connection usually employed. The loop, *a*, is made of a piece of thick, hard leather—a piece of an old harness tug, or a strip of sole leather is good. The leather is cut about an inch and a quarter wide, and formed into a loop with the ends lapping as shown at *b*. A hole is made through the lapped ends, to receive a round-headed bolt. This bolt has a pin-hole, *c*, at its lower end. The bolt is now driven into the handle *d*, and the pin *e* inserted, which holds the bolt in place. A piece of tough leather

A SIMPLE FLAIL.

thong, *f*, is put through the leather loop *a*, to unite the two parts of the flail. This loop *a* swivels on the bolt *b*. This is firmly fastened in the handle.

Live-Forever as a Weed.

Several of our troublesome weeds are escapes from cultivation, as may be conspicuously seen in the Wild Parsnips and Wild Carrots. These are degenerate useful plants, and the Toad-flax (*Linaria vulgaris*), is a quite too common example of an ornamental plant that has gone astray. This showy plant was cultivated by our grand parents, as "Butter and Eggs." A Mr. Ranstead had it in his garden near Philadelphia, and the plant is known in Pennsylvania as "Ranstead Weed." Live-forever is another ornamental plant, that has escaped and become a weed. Mr. "J. E. B.," Little Falls, N. Y., sends a specimen of a weed known as Live-forever, and wishes to know about the plant, and how to get rid of it. Live-forever, as a weed, is of comparatively recent occurrence. It is a species of Stone-crop (or *Sedum*). Its numerous stems form a clump, which, when in flower, is quite handsome. We can remember when it was grown in gardens for its beauty and as a curiosity. A well established clump has numerous fleshy stems a foot or more high. The ovate leaves are very thick, and each stem is terminated in mid-summer by a large, flat cluster of light-purple flowers. The stems are very tenacious of life. A full-grown shoot, fastened by a pin against a window sash, instead of wilting will go on and perfect its flower cluster and bloom from the nutriment stored up in the thick stem. While this peculiarity of the plant made it an interesting one, its strong hold upon life, and the fact that every fragment of the stem in contact with the soil, will strike root and form a new plant, make it very formidable as a weed. In many places where it has gained a foot-hold it shows every disposition to stay. Its reproductive powers are so marked that breaking up the old plants by plowing or digging only increases the trouble, as every stem, or fragment of one, will form a new clump. European works upon agriculture do not mention Live-forever as a specially troublesome weed, yet in this country it has in many places established itself, and its eradication is already a serious problem. The subject was brought to the attention of our readers several years ago. One correspondent then reported success with smothering the plants, placing upon them small heaps of manure, or covering them with bog-hay, or whatever would exclude light and air. A few clumps can be thus treated, but where the plant, as in some cases, has taken possession of the ground, smothering is not easily practised.

With this, as with all other weeds, "resist the beginning" is the true method. The farmer should know all plants by sight. Those not known to be of use may be regarded as enemies. If upon the first appearance of a stranger, he is questioned as to his objects, much trouble may be saved. Let those who have successfully exterminated "Live-forever" report their methods of dealing with this weed. The pest is increasing.

Patents, and Patent Laws.

That the farmer who, finding a design for a gate in the *American Agriculturist*, or other journal, has built one from it, should feel aggrieved when some one subsequently calls upon him and demands a royalty, is not at all surprising. Another farmer has read that the patent on the driven-well is not valid, puts down the tubes for such a well, and soon finds himself obliged to pay a royalty, or to stand a suit at law. He of course feels that he has been wronged, and looks upon all patents as frauds. These gates of different kinds, and the driven well, are but examples. There is scarcely any other device used by the farmer, even if of his own invention, for which he may not be called upon to respond—honestly it may be, but often dishonestly—for an infringement of somebody's patent. Such cases have occurred so frequently, especially in the Western States, that farmers—and we do not wonder at it—have become exasperated. They have now, through their granges, clubs, and other associations, made themselves heard by their members of Congress, in their demands for relief. As a consequence, bills have been introduced, looking to the abolishing of the patent office. Hasty legislation is undesirable at all times, and would be especially unfortunate in the present case. While general attention is called to the matter, the present is a good time to revise our patent laws, and endeavor to remove their objectionable features. Our present system, liable as it is to abuse, is vastly better than none at all. In agriculture alone, the patented inventions have been of a benefit that can not be computed. The present mowers, reapers, headers, threshers and a host of other farm machines, would never have been in use, could not the inventors have been able to patent them. One must be short-sighted, who can not see that patents have done much to advance our agriculture. Our patent system is open to abuse, and no doubt has been made use of by swindlers. That this is the case, is not so much the fault of the patent laws as of the farmers themselves. If the farmers of every township, or school district, had an association, the members of which would make common cause against all frauds who claim to have patents on the commonest farm devices, and instead of compromising these claims, could contest them, this would usually be the last of them. When our Patent Rules are revised, and the present seems a good time for doing it, we would suggest that much of the trivial stuff that is now patented, be rejected altogether. The present rule seems to be, to give a patent to everything that has not been patented before. A farmer may have used a simple device for many years, some sharp fellow coming along sees it, and procuring a patent, may prevent the farmer from using his own invention, unless he pays a royalty. Abuses of this kind are not rare; they should be made impossible. At present a patent is worth nothing to the inventor, until he has been at the expense of defending it in the courts. The government should keep out all the trivial stuff, and allow patents for only really useful and important inventions, and having once granted a patent, and taken pay for it, should defend it in the courts without cost to the inventor. A treaty, which has been made by representatives of our own, European and South American Governments, has been presented to the Senate. The nations in this union or league, agree that a patent granted in any one of these countries, shall be valid in all the others. This scheme seems to be favorable to our own inventors. But the people have something to say, as well as inventors, and before concerning ourselves

with our foreign relations, let us have patent laws that are acceptable to farmers and others at home, and not be open to the abuses at present possible.

The Farm Workshop.

The farm workshop should be conveniently located as to both house and barns. Some of the operations to be performed therein will require the use of a fire, more particularly so in the winter, and therefore place the shop so that the strongest prevailing winds will carry all sparks away from other buildings. The size, character, and style of the building will vary with the means and taste of each builder. In length, it should give ample room for a board sixteen feet long, and wide enough to accommodate a good work-bench, leaving room to run a wagon in alongside, with plenty of space on each side to work at any part to good advantage. The height should be at least eight feet to the eaves, and the roof may be either flat, span, or lean-to, as the builder desires, only it must be waterproof.

The elevations and plan, figures 1, 2 and 3, show a building twelve by twenty feet on the ground, and eight feet high, which will give plenty of room for all ordinary work. To build this will require about eight hundred feet of one-inch lumber, eight feet long, for sides and roof; two pieces two by six, twenty feet long; two pieces two by six, twelve feet long; eight pieces two by four, twenty feet long; four pieces two by four, twelve feet long, and eighty feet flooring for doors. The windows as shown in figures 1 and 2, are of eight by ten glass.

Fig. 1.

Fig. 2.

Figure 4 shows how the sills and plates are placed. The siding, eight feet long, running up and down, is nailed firmly to the plates and sills. The gables are covered with lumber, lapping down over the ends six inches. The roof boards, eight feet long, run up and down, and are nailed securely to the plates, the ridge, and pieces between.

The roof should be covered with a sheathing of tarred-paper and shingled, or what is preferable, with a roofing of asbestos, which, if laid according to directions, will give a firm, lasting, and fire-proof roof. The sides may be simply battened, or what is far better, covered with a water-proof sheathing, battened and well painted. The extra cost of the sheathing will be repaid many times in comfort in cold, wet weather. The doors are made of flooring, having battens firmly fastened on with wrought nails, and hung with heavy strap-hinges. The large door should be hung to swing outwards, and can be

Fig. 3.

Fig. 4.

fastened by bolting a piece of two by four scantling on the front edge. The small door can swing inward and be provided with a strong lock and a latch.

There should be four or five boards nailed firmly to the under side of the plates and center-piece, as shown at *a* in figure 4. These may be of any width, the wider the better. Place a board through the center, and another midway each side of this; they will prevent the sides from being pushed apart by weight on the roof. Nail three or four boards from the center-piece to the ridge pole. The space under the roof can be utilized for storing odd pieces of lumber, etc., where it will season thoroughly, and be convenient when wanted.

Figure 3 shows the location of the work-bench *a*, foot-lathe *b*, anvil *c*, forge *d*, and the coal barrel *e*.

Aprons for Horses.

Horses, while at work should have some protection from the bot-flies, which lay their eggs upon their shoulders, neck and gullet during the summer months. An apron may be made of any coarse cloth, and fastened to the lower part of the collar, as shown at *d* in the engraving. The horse is most annoyed by the bot-flies when they dart under and strike the throat. To prevent this, a cloth

PROTECTIONS FROM FLIES.

can be fastened to the bit-rings and throat-latch, seen at *b*, thereby very materially adding to the comfort of the animal. Nervous horses are much more annoyed than others, some of them being almost frantic if not protected when the bot-flies are at their worst.

The Farmer's Liability for the Acts of His Beasts.

H. A. HAIGH.

GENERAL RULE AS TO TRESPASSES.—It is the duty of every one to keep his domestic animals upon his own premises. This duty extends to his own animals, and those that are entrusted to his keeping. If he fails to perform this duty, and the animals escape and go upon other person's lands, and there do injury, it is a trespass for which an action will lie, and damages may be recovered.

EXCEPTIONS TO GENERAL RULE.—This general statement is modified by the fact, that where the owner of lands trespassed upon is under obligation to keep them fenced against these particular animals, and he fails to do it, then no damages can be recovered. Such an obligation may arise by agreement between the owner of the land, and the owner of the trespassing animals; or it may be imposed by law, as, for example, the statutes requiring adjoining owners of improved lands to maintain the division fence between them in equal shares; or it may come about by custom, as is possibly the case in some of the newer States, where the universal custom of allowing domestic animals to run at large upon unenclosed lands, may have created an implied license for such animals to enter lands that are not enclosed with fences. But where fence regulations have been complied with, and domestic animals trespass notwithstanding, then their owners are clearly liable for the usual injuries resulting from such trespasses, like grazing off and trampling down grass, grain, or other crops.

INJURIES BY VICIOUS ANIMALS.—For the vicious acts of unruly domestic animals, like kicking, hooking or biting, the owner is generally liable. If a man owns an ugly beast, prone to do harm, it is his duty to prevent it from doing injury, both on his own premises and everywhere else, so that people may not suffer from its dangerous disposition. He must use due care to prevent any harm resulting from its evil propensity, and his liability will depend upon some negligence on his part, some

failure of his duty to exercise due care. Of course if he does not know that the beast is dangerous, he cannot be expected or required to take extra precautions; if he has not had what in law amounts to notice of the evil disposition, he cannot be held liable for not guarding against it. Consequently, where a horse or an ox suddenly, and without any previous exhibition of bad temper, does a vicious act, like kicking or hooking a bystander, its owner is not, and in reason should not be, held liable. As to what amounts to notice of a vicious temper, the rule is that it should be sufficient to put a prudent man on his guard. It is not necessary that the animal should have already done harmful and vicious acts; if it has manifested a disposition to do such things, that is sufficient to notify the owner of the danger (25 Conn., 92). The notice, however, in order to lay the duty of precaution upon the owner, must be notice of a propensity to do the particular mischief that has been done. Notice that a dog will worry sheep, is not notice that he will attack a person (66 Ill., 309), or is notice that a horse will run away, notice that he will bite (11 Ind., 269); though it has been held that notice that a bull will attack and gore other cattle, is sufficient notice that he would so attack persons (27 Pa. St., 331). And there are certain kinds of mischief, which certain animals—for example, stallions—are prone by nature to do at a certain time of the year, and these must be guarded against by the owner, without any previous warning (26 Ind., 334).

It is no defense to a vicious injury by a domestic animal, that it was committed on the owner's own premises, and that the person injured was at the time a trespasser (17 Wend., 496). A man cannot defend his premises by such means as a ferocious beast, any more than by setting man-traps, or spring-guns (37 Iowa, 613). So, therefore, if the farmer keeps a savage dog, allows him to go unrestrained about the farm, and he attacks and injures a person who is casually crossing the land, the farmer will be liable, nay more, if the person be at the time a trespasser, hunting in the farmer's woods on Sunday, the farmer will have to pay for his lacerated legs, although he did not set on the dog (17 Wend., 497). Likewise, if the farmer has an ugly and ferocious bull, which he allows to traverse through his fields, and the animal pitches upon strolling fishermen, trespassers though they be, the farmer will have to pay for their broken ribs, or broken necks, as the case may be (3 C. & P., 138; 124 Mass., 49). One may doubtless defend his house against burglars by a savage dog, but if it bites and injures any one coming to the house on any innocent purpose, he will have to pay for the damage (41 Cal., 138). Some sort of negligence, however, on the part of the owner of the unruly beast, is necessary to create a liability. If one's horse breaks loose from him and runs away in the street, and there injures some one, or smashes a carriage, he is not liable merely because the horse got away. Some negligence must be shown, as that he left the horse unhitched, or his harness or wagon was known by him to be out of order, or unroadworthy, etc. (3 Allen, 565).

CONTRIBUTORY NEGLIGENCE EXCUSES.—As the right to damages depends upon negligence on the part of the owner, any contributory negligence on the part of the person injured, excuses the owner and relieves him from liability. It would be obviously unjust to allow a man to recover damages for an injury which he himself helped to bring about. Consequently, if I go into my neighbor's pasture, and begin teasing his mad bull, I cannot complain if the bull tosses me over the fence, and injures me in so doing. Undoubtedly it was negligence for my neighbor to keep such a savage animal unconfined, but it was also negligence for me to place myself needlessly in its way. But if my little children, not yet old enough to know the harm of going near, or teasing a fierce bull, went there in play and were injured, without any fault on my part, then the principle would not apply (4 Allen, 431; 10 Cox, 162).

INJURIES BY WILD BEASTS.—Formerly the mere keeping of a wild and ferocious beast, was of itself negligence; at least, damages might be recovered for the injuries done by one, without alleging negli-

gence on the part of its owner (9 Q. B., 101); but this is not now the case. The keeping of wild beasts for exhibition, and the entertainment and instruction of the public, is now a legitimate business, and all that can be demanded of their keepers, is the highest degree of care and caution, and if, notwithstanding these, they manage to get loose, and do harm, it must be referred to the category of accidental injuries, without ground for action (8 Barb., 630). It is no longer unlawful to parade some wild animals, as elephants and camels, on the public streets. If a horse is frightened by the mere appearance of these, and runs away and does damage, the owner of the elephant or camel is not responsible (38 Barb., 14).

As to the liabilities of owners of dogs, for injuries done by them, the statutes of nearly, if not all of the States, have made provision. It would require too much space to give even an analysis of these statutes. Generally they remove the necessity of proving a *scienter*, that is, that the owner had knowledge of the dog's vicious disposition. The effect of them is generally to presume all dogs ugly, and to make the owners liable, irrespective of their knowledge on that point.

Beets Early and Late.

In most gardens it is customary to make a sowing of some early beet, and after the crop from this is used up, the table is supplied from the rows of the Long Smooth Blood, or other long and late variety. While the last named is the best of the late beets, it is, at its best, vastly inferior to the small early kinds. We regard the Early Egyptian as the finest beet with which we are acquainted. The Early Blood Turnip Beet is larger than the Egyptian, and while not quite equal to it in quality, is still a very good and useful variety. We manage to have one or the other of these all through summer and autumn, and usually our winter's supply is of the Blood Turnip, instead of the longer kinds. The Egyptian is sown every ten days until July, when abundant sowings of the Blood Turnip are made, to be used when large enough, and to have a sufficient supply for winter. In all sowings of beet seed, we sow with a free hand, with a view to abundant thinnings, which, of any beet, are the best summer greens. In growing early beets, we are apt to leave them too close together; five inches apart in the rows is quite near enough; those intended for winter may be thinned still more by pulling the roots, as wanted to supply the kitchen, from those parts of the rows in which the beets are the thickest. In storing beets for winter, be careful that they do not shrivel; covering the roots with sand prevents this and keeps them fresh.

A Land Measurer.

An instrument for measuring land is shown in the engraving. It consists of a wooden handle, into the bottom of which are fastened two stout curved iron rods. A cross-bar, bolted to one rod, and secured to the other with a thumb-screw, sets

A LAND MEASURER.

the ends of the two rods at the desired distance apart. The measurer may be arranged so that the distance is one quarter of a rod, or it may be more or less. The implement is taken in one hand, and alternately turned upon each leg or end of the rod. It is only necessary to keep moving in a straight line. Measuring in this way is much more accurate than pacing, and may be done almost as rapidly.

The Improved English Shire Horse.

Our breeders are awake to the fact that there is much good material in the English Shire horse, inasmuch as they are importing descendants of this stock more largely than at any former time. Great ungainly brutes they were, but having been improved by judicious crosses and selections, they are no longer looked upon as mere elephantine masses of flesh and bone. When bred with care they rival the Clydes and Normans for form, style, nerve, power, docility, and endurance, while for size they are simply stupendous. They offer grand stock to build upon, having a relation to the finer and high-bred races the qualities, as it were, of a rich soil, abundant nutrition. The cross will "nick well," provided it be not too violent, and the foal has the best possible chance for full development and vigorous growth, both before and after birth. How often we overlook the importance of a good dam. No breeder should ever breed from a poor one with any expectation of improvement. Her influence extends for generations, usually alternating with the sex of the progeny. Thus the sons of a fine mare will be more likely to reproduce her good qualities in their daughters, than will the mare herself in her own daughters; the latter will very likely reflect their sires' rather than their dams' good points. The improved horses, a superb example of which is shown in the engraving, are firm in

bone and compact in every way without deterioration in weight. They are said to look like smaller horses, but to weigh much heavier than they look, and that is the secret of their excellence. If great soft bones, flabby muscles, and fat be compared with fine, hard, solid bone and flesh, easily kept in condition, there will be found naturally greater weight, greater power, greater endurance, a better constitution, and greater value. The old style of mares have grand digestion and great capacity for turning hay and grass into flesh and milk. They were not easy keepers, but great producers, like the big milking cows. Their progeny are, therefore, splendidly developed, share the finer and firmer qualities of their sires, their nerve power and willingness to work, as well as the strong muscles to do it. They inherit and transmit also to their daughters, the valuable qualities of their dams, weight, feeding capacity, constitution, etc., and so we have great improvement, and may look for still greater. The horse shown in the engraving recently won the first prize as a three-year-old at the Derby Royal Agricultural Show, and has twice been champion stallion at the Horse Show in London. In show order, he weighs two thousand five hundred and twenty-six pounds—a truly enormous weight for so young a horse. He is seventeen hands and one inch high, ninety-eight inches in girth, one hundred and two inches around the belly. His fore-arm measures thirty and a half inches around, and the fore-leg below the knee twelve and a half, the hind-leg below the hock fifteen, the thigh above the hock twenty-four and a quarter, and his height to top of quarters is sixty-eight and a half inches. He is the property of Mr. Walter Gibbey, the President of the English Shire Horse Society.

When this stock is acclimated in this country, and improved by breeding, we may expect it to become the foundation of a valuable race of work-horses.

The North Carolina Phosphates.

DR. CHAS. W. DABNEY, DIRECTOR NORTH CAROLINA EXPERIMENT STATION.

The phosphates recently discovered in North Carolina will undoubtedly take an important place in the trade, and, in time, reduce the cost of all superphosphates. This North Carolina rock is very massive near the surface, and convenient to

cents per ton. When we recall how great the reduction in the price of all fertilizers has been since the South Carolina phosphate mines were opened, the significance of this discovery for all farmers, who buy any manures, based upon superphosphates, will be apparent. The first North Carolina phosphate found was of low grade, containing from thirty to forty per cent of phosphate of lime. Recently extensive beds have been discovered, yielding rock fully equal to that of South Carolina, of which fifty-five per cent is the usual standard. The rock crushes and grinds well, as it is extremely brittle. This latter property is due to the small per cent of sand,

which is the leading impurity, and of all adulterating materials the one least objectionable. The South Carolina phosphate is mixed with carbonate of lime, oxide of iron, and alumina, all of which combine with sulphuric acid, when the rock comes to be made into superphosphate. Acid must be added for these as well as to dissolve the phosphate, and when it has been dissolved, they are the main cause of that retrograde action, known as reversion of phosphoric acid. The North Carolina rock contains very little carbonate, iron, or alumina, and requires one-fourth less acid than the South Carolina rock. The sand is entirely neutral toward the acid. This is another point in favor of the North Carolina rock, which farmers as well as manufacturers will appreciate. These phosphatic rocks have laid in their beds for untold ages. The virgin soil of a new country did not need them. Wasteful farming soon exhausted the soil, and when needed to return lost fertility, these phosphates came to light. So when whales became scarce, and oil dear, heretofore unsuspected stores were discovered. What else has nature in store for us?

AN OLD ENGLISH SHIRE HORSE.—Engraved for the American Agriculturist.

the lines of transportation. That it is found in sand and not in clay, as is the South Carolina rock, is a point very much in its favor. The latter rock is so porous and full of holes, as to require breaking up and washing, to rid it of the clay. The North Carolina rock lies in a sand or loam, and can be dug out in large rounded lumps, from which the sand may be brushed off without difficulty.

In South Carolina, the rock is mined in open ditches, thrown out upon the bank with the accompanying clay, and a large per cent of water, and wheeled to the railroad, and shipped on cars to the washing and drying works. At the washing establishment this rock is broken, run through a washing machine, fed usually by a large force-pump, and finally dried by artificial heat. The North Carolina rock is easier to mine from the loose sand or loam. It occurs at about the same depth, but the amount obtained per acre is much greater. In a number of trial pits, the yield was eight hundred tons per acre. This is a very remarkable output. The North Carolina rock can be delivered on the bank, and loaded on the cars with only four per cent of earth adhering to it. A simple brushing-machine will remove this.

Rock in this condition, directly from the pits, contains not exceeding one per cent of water. South Carolina rock is always dried twice, once by the miner before it is sold, and again by the manufacturer. The North Carolina rock would not need drying at all, except to make it grind better. The great saving in preparing the rock for market is thus apparent. While six dollars per ton is the lowest figure ever reached by South Carolina phosphate rock, this North Carolina rock can be sold, delivered on the railroad, at three dollars and fifty

Why the Potato Experiments Differ.

We have a great variety of experiments with seed potatoes, from experiment stations, model farms, and amateur farmers, showing the great advantage of large and small potatoes, seed-end and stem-end, whole seed and cut, eyes with much flesh, and mere parings; leading the reader to contradictory conclusions, and making of the seed question a muddle. In many cases the story is only half told, and the factors in the case, aside from the particular treatment of the seed, are overlooked. The condition of the soil, fine or lumpy, rich or poor, the character of the season, wet or dry; the cultivation, little or much, have quite as much to do with the success of the crop, as the state of the seed. The contradictory results so often reached by intelligent and fair-minded men, emphasize the great importance of a thorough preparation of the soil, making it well pulverized, well manured, and well drained. Maximum crops, three hundred to five hundred bushels to the acre, can only be had where there is this thorough preparation of the soil, until the vines are in blossom. The average yield of potatoes in many farming districts with any treatment of seed is not much over a hundred, if it equals it.

Walks and Talks on the Farm.

New Series.—No. 1.

JOSEPH HARRIS, M. S.

It is over eight years since the last number of my "Walks and Talks on the Farm" appeared in the *American Agriculturist*. Since then, my good friend and neighbor, the Deacon, and I have had many walks and talks together on the farm. The Deacon's farm has greatly improved. A portion of his land has been underdrained and produces splendid crops. He plows earlier and cultivates more thoroughly, and if he is not careful he will soon be a model farmer. I do not think he keeps any more stock or makes any more or better manure, but he grows better and cleaner crops simply because he works his land better. Like most of the farmers in this section, he has been using more or less phosphates, especially for winter wheat. Sometimes he thinks it pays and sometimes not. The truth is, that nearly half of my farm and the Deacon's consist of low, mucky land which, if partially drained and well worked, will yield good crops with little or no manure. Last year the Deacon raised an acre or more of good winter cabbages on this black mucky soil without any manure. And land which is rich enough to produce good cabbage, certainly will produce ordinary farm crops, such as corn, oats, potatoes, and grass. Adjoining the cabbages, on similar land, he sowed a few acres of millet and had a splendid crop; the land was left remarkably clean and in good condition. The other half of the Deacon's farm consists of higher, drier, and poorer land—but which, when thoroughly cultivated and kept free from weeds, will produce good crops of wheat, beans, corn, and clover.

I have always told the Deacon, that the best way to manage his farm was to keep more stock and make more manure, even if he had to buy bran, malt-sprouts, and corn, to feed the animals in connection with the coarse fodder raised on the farm. I have not converted the Deacon and never shall, though I felt strong hopes of him last spring when he set out an acre of cabbages. He had so much success with them, that doubtless he will continue to grow cabbages as a farm crop for years to come.

On my own farm there has been no change in the management during the last nine years. I continue to keep a large amount of stock, and to buy considerable food for them, especially that which will make rich manure. I have adopted this method for about twenty years, and I see no reason for changing it.

Even the Deacon agrees with me now, that the plan, in my circumstances, is a good one. He criticized me formerly, because he did not understand what I was aiming at. He thought I was buying feed and consuming nearly everything that I raised on the farm, in order to make manure for growing ordinary farm crops. He thought it would not pay. He may be right, though I think much might be said on the other side.

In my own case, however, I use manure for growing mangel-wurtzel, beets, carrots, parsnips, cabbages, onions, and similar crops, which can only be grown on the richest and cleanest of land. During the last eight years, I have greatly extended the area of land devoted to these crops. I can not compete with the Rochester nurserymen in buying manure from the city stables. It is too far to draw it and they take all there is. I am obliged to make my own. What I make is far richer in plant-food and more valuable than any I could buy. During the last eight years the price of superphosphate has been reduced and the quality improved. I use it freely and with great advantage.

The Deacon and I are eight years older. Twenty years ago this spring, I set out about a hundred Norway spruces. They are now over forty feet high. They are beautiful, healthy, and vigorous. When I think how small they were when I set them out, and what magnificent trees they are now, I feel that the years are steadily advancing and that I must be getting older. So of my Northern Spy apple orchard. The trees have grown until the branches almost meet, and what is better, they bear

fruit abundantly every year. There has been no change in the management of the orchard during the last seventeen years, during which time it has been in grass. The trees were set out in 1857, and for the first ten years the land was planted with corn, potatoes, etc. Since the trees commenced to bear, the land has been kept as a pasture for sheep and pigs. It has been repeatedly top-dressed with manure. And whenever we have any weeds or rubbish of any kind, it is drawn into the orchard and spread over the land. It is convenient to have such a place. We are never at a loss where to put weed-seeds, coal-ashes, refuse lime, turnip, beet, and cabbage leaves, carrot and parsnip tops. Anything that will make manure or mulch the land, anything that the pigs will eat in whole or in part is taken to the orchard. In this way the land has become exceedingly rich. In the spring, the moment the snow is off the land, the grass begins to start and we soon have a fine bite for the ewes and lambs. And all through the season, no matter how dry it is, we are always sure of a little good pasture in the orchard. I am so well satisfied with the advantages of this method of managing an orchard, that I have set out several acres of apple trees near the barn-yard, with the ultimate intention of seeding it down to grass and keeping it as a permanent pasture. In the meantime I keep the land between the rows of trees under cultivation. In fact, I am using the land as a Field-Garden. It is heavily manured, carefully and repeatedly plowed late in the autumn and early in the spring, and worked into the finest condition for hoed crops, drilled in wide enough apart to admit the use of a cultivator. We only cultivate one way; and between the rows of apple trees, running in the direction in which we cultivate, we set out currant bushes which now bear large crops. It takes a good many years to make our dry, sandy upland rich enough for permanent pasture. But I think the above method will accomplish the object, and in the meantime much more than pay its own way. I do not say that this is the best method of preparing land for a permanent pasture. It depends on circumstances.

Five years ago I was at Rothamsted, after an absence of thirty years. Mr. Lawes, or Sir John Bennett Lawes, as he now is called, in recognition of his pre-eminent services in the field of agricultural research, has converted many acres of the land formerly under tillage into permanent pasture. A fine herd of Hereford steers were grazing on the land. It was stocked heavy enough to keep the grass well cropped, and the steers were fed every day all the American cotton-seed cake they would eat. Of all vegetable substances, there is nothing which makes such rich manure as cotton-seed cake. It may not be as nutritious as linseed cake, but it is richer in nitrogen, phosphates and potash. And as Dr. Veleker well remarked, it has this practical advantage: You can feed fattening cattle or sheep all they will eat. They will not eat too much. With linseed-oil cake, corn and other grain, as we all know, we have to be careful every day to measure out the proper allowance. It is necessary to have a reliable man do the feeding, or some days the animals will get too much and some days too little, and their digestive organs are soon out of order.

In process of time any pasture land stocked with cattle or sheep having an unlimited supply of cotton-seed cake, must get very rich, and there are many places in this country where the plan could be adopted to advantage. Such, for instance, as the so-called barrens of Long Island, and hundreds of thousands of acres on the Atlantic slope. There is also much hilly land which is now comparatively unproductive, and on which it would be an expensive operation, even if we had it, to draw manure. This poor land may be slowly and surely reclaimed by stocking it with sheep or cattle, and feeding them all the cotton-seed cake they would eat.

Since we last wrote these Walks and Talks on the Farm, the subject of ensilage has attracted much attention. Its success is mainly due to the fact that corn fodder is one of the most profitable crops which can be grown for feeding cattle,

horses and sheep. The advocates of ensilage have done much good by calling attention to the great value of corn fodder. Whether it is better to cure the fodder or to preserve it in the green state, is a question of cost. One fact should not be overlooked; our dry, hot climate is admirably adapted, not only for growing the corn-fodder, but also for curing it. I cut my corn-fodder with a self-raking reaper, tie it into bundles, stand it up in small shocks, and afterwards put nine of these shocks into one large central shock, carefully made and tied at the top with willow or rye-straw bands. If properly made, the corn-fodder keeps perfectly in these large shocks, and can be drawn in from time to time during the winter—drawing, of course, as much at one time as can be properly stored away.

One of the most remarkable changes which has taken place in our agriculture during the past eight years is the general use of superphosphate for winter wheat. That it pays the farmers to use it, there can be no doubt. Farmers are not inclined to make accurate experiments; but they do not continue to pay out money year after year for an article the use of which is unprofitable. How long the use of phosphates will continue profitable, will depend on the amount of organic matter existing in the soil, and upon the use which is made of the increased crops obtained from the use of the phosphates. If all the crops are sold off the farm, we should soon, except in rare cases, so far impoverish the soil that profitable crops could not be grown. On the other hand, if we use the money obtained from the increased crops of wheat, barley, potatoes, vegetables, etc., to buy a small amount of bran, cotton-seed cake, malt-sprouts, etc., to feed out in connection with our straw, corn-fodder, clover hay, etc., the use of phosphates will enrich rather than impoverish the land.

Year before last the wheat crop in this section was the best I have known for thirty-two years. The Deacon has lived here much longer than this, and he says he has never before known so good a crop. And farmers who cleared up the land from the original forest say the same thing. One of them told me—and he is a reliable man—that he got fifteen hundred bushels of wheat from thirty acres. It was not phosphates in this case; he drilled in ashes and plaster; but it was not ashes and plaster that produced the crop. Whatever the cause, it is evident that our soils are still capable of producing good crops of wheat.

One thing is certain, our farmers as a rule are working their land better than formerly. We have better plows, better cultivators, better harrows, better rollers, and better horse-hoes, though the latter are not half as good as they ought to be. We do more fall-plowing. Even the Deacon harrowed his corn-stubble last fall, and got it ready to drill in oats this spring. We are getting more and more in the habit of preparing our land in the autumn. The Deacon is not here to-day, or perhaps he might dispute some of these statements.

"Hard times"—I should say so. But the American farmer is not a grumbler—certainly not when he has good cause to grumble. He is one of the most hopeful and energetic of men. Last year, he had no wheat, no beans, no fruit. He had good potatoes, but the price was so low that they hardly paid for digging and marketing. He had a great crop of oats, and a fair crop of hay, but the crops he depended on to bring in the money were essentially a failure. My own wheat crop was the poorest I have known for thirty-four years. But we have lived through it. And to-day (June 2), the country never looked more beautiful, or the prospects brighter. Some farmers say the dry weather in April gave the wheat a set-back. But, as a rule, our wheat never looked better. We feel decidedly encouraged, and look for better times.

I was in New York last week, and called at the *American Agriculturist* office. They seemed pleased to see me. The truth is, the editors look more like farmers than city people. The managing editor was in his shirt-sleeves, and works as hard as any

farmer I know. I was not surprised to learn that the *American Agriculturist* was never in more prosperous circumstances than at the present time. It is certainly a noble paper for everybody.

Fine Action and Good Gaits in Horses.

Good gaits and fine showy action in a horse add greatly to his value. They are not altogether brought about by training, though this does a great deal. Many a well formed man, especially if he grew fast when a boy, and was laughed at and felt awkward, goes through life with the style of a shy, shambling, bashful lad. Very likely he never stands erect, carries one shoulder higher than the other, his head on one side and even walks half sideways and does not know it. It is just so with horses. If a farmer's team comes into the city trainer's hands at four to six years old, even if dull, stupid, and laggard, they will wake up to business, and in two months even their breeder will not know them. They will hold their heads high, pick up their feet with life and put them down as if they were not afraid. Altogether there will be the style of life and training, as if they knew they were well trained and were proud of the show. At seven or eight years old it is too late, they will be a plow team to the end. This sort of style is all but essential for carriage and road horses, but another sort is needed for the particularly useful gaits of horses of all work, namely, the walk and the trot, both in carrying heavy loads and with very light ones.

All the training in the world will not give a horse good legs, and with this wanting, the spirit and the sort of style which is developed by training and oats, counts in real work and service for very little. A horse needs both, and then there is some hope for him. With a good set of legs the trainer has the right foundation to build upon. It is quite a "point," as they say "on the street" to know good legs when you see them. It does not take an expert to tell if a set of legs look all right from the side, when the horse is either still or in action, but the real points of views to judge critically are directly in front or behind. We give three styles of legs by which all may be classified, as they vary from the perfect form towards either extreme. No. 1 in each set represents the perfect pair of legs. The feet point directly forward, are round, well up at the heels, large, solid, and free from either grooves and ridges running up and down, or from irregularity in the lines of growth, which always form fine parallel striæ in a healthy hoof. It is a suspicious circumstance if these are filed off and the hoof made smooth. The fact is, nothing is a surer index of previous good health than the hoof. If a horse has a fit of sickness the hoofs

Fig. 1.—GOOD AND BAD FORE-LEGS.

cease growing, and when they begin again with returning health they all show a ridge, so if from any cause one foot is effected by fever, or a wound, it alone will show it almost certainly by increased or decreased growth, as the case may be. The joints are large, hard, bony, and free from meat or puffs. Below the hocks and knees the bone of the leg is flat, and of good size for the weight of the animal; the cords are hard as bone, free from muscle, and the skin free from scars and drawn tightly over the whole. Avoid slender pasterns. The pastern bones and those forming the pedal joint should have all the breadth and solidity possible. The muscular portion of the legs—the fore arms and the thighs—should be large and even, and the

muscles should stand out individually distinct and hard. The whole leg should be almost perfectly straight, that is perpendicular, as indicated by the lines drawn through No. 1 in each set.

When the hoofs point out, the knees and hocks tend inward, as shown in No. 2 of each set, and when the hoofs point in the knees and hocks are thrown outward in a less obvious, but yet in an awkward way. This is shown in No. 3. With the

Fig. 2.—THREE SETS OF HIND-LEGS.

idea clearly in his mind and a little observation, one will soon be able to recognize a good and also a bad set of legs on almost any style of horse.

Fill up the Vacancies.

Hills are sometimes missing in the corn-field, from poor seed, erows, cut-worms and other causes. It does not pay to leave these places vacant. If replanted, they may produce good fodder, even when too late for ears to form. Idle land will produce a crop of weeds, which, by going to seed, bring trouble for many succeeding years. It is well to replant with a smaller and quicker growing variety, that will yet have time to mature. The two sorts will not mix badly, because the periods for crossing come at different times. The appearance of a corn field is much improved by filling up the vacant hills. We have known of replanting being done as late as July, and the labor rewarded with a fair crop of soft corn for the pigs, besides a heavy growth of excellent fodder. A considerable area where corn or some other crop has failed may sometimes be profitably sown to buckwheat.

Feeding the Silk-worm.

M. J. G. HAMMACK.

There are three kinds of silk-worms: Annuals, Bivoltines, and Trivoltines. The Annuals produce but one brood a year, Bivoltines two broods, and Trivoltines three. After considerable experience we are satisfied, that the last two breeds cannot be raised as profitably as the pure Annuals. Annuals' eggs will not hatch prematurely, but the hatching cannot be deferred for any length of time, after the trees are in leaf, except by using ice, in which case the vitality of the eggs is more or less injured. It is necessary, in any climate, to watch the advance of the mulberry tree in the spring.

The following are some of the terms used in silk culture: grain is silk-worm eggs; the cocoonery is a house where the worms are raised; moulting is the time at which the worms change their skins. Chrysalis is the form assumed by the worm inside the cocoon. Floss silk is loose silk that envelops the cocoon, and is earded and spun like cotton. The cocoon is the silken covering with which the worm surrounds itself before passing into the chrysalis state. Raw silk is silk that is reeled from cocoons. The ages are periods between two moults; green-cocoons is a name frequently applied to fresh or unhatched cocoons. Pierced cocoons are those that the moth is allowed to perforate, and are sold for waste silk. Choked cocoons are those stifled, or have the chrysalis killed, by steam or in the hot sun. Litter is the accumulation where the worms lay, of dried and partly consumed leaves, and offal of the worms themselves.

GATHERING THE LEAVES.—If the trees are desired for standards, at two years old, they may be stripped of their leaves. The leaves must not be gathered before sunrise or after sunset, when dew

or fog makes them damp. They should be gathered before nine o'clock in the morning for the day's feed, and before seven o'clock in the evening for the morning's feed. If leaves are dusty, they should be wiped with a dry cloth. In case of threatened rain, leaves may be gathered two days ahead, and kept in a cool place. If it should become a necessity to gather leaves in the rain, spread them out on the floor in the shade in an airy place, or dry them by shaking in a sheet. Give to the young worms the best, tender leaves, after the second moult. After the last moult, give to the worms the thickest and best leaves the trees produce.

Silk-worms should be fed during the day and night, from the hatching to the spinning time. Give them all they can eat, at regular hours. Worms matured in twenty-five or thirty days will produce more silk, and of a finer quality, than those fed forty days, and the short-lived worms are less liable to disease. Worms will never leave the feeding shelves if properly fed. The worms should receive light meals, first, at six in the morning; second, at eight; third, at ten; noon, two o'clock, four, six, eight, and ten. In very warm weather, an extra feed should be given at midnight. On cool days the worms will consume less food than in warm ones. The young silk-worms should have one single layer of chopped leaves for their meals, and if these become dry, feed again in half an hour.

Raising Seeds.

We are asked why we do not encourage people to raise their own seeds, instead of buying them every year. Seed-raising is an art, and requires more care than the average farmer can afford to give to it. Seedsmen have their seeds raised by men who make a business of it, who grow but one variety of a kind, and avoid all chance of "mixing" or crossing. One who has a garden can hardly be persuaded to select his first ripened tomatoes or Lima beans for seed; he wishes these for the table. Unless a vegetable can be kept up to its best condition it will deteriorate. Take tomatoes for example; the plants should be raised expressly for seed. As soon as they come into bearing, every plant that does not have fruit quite up to the best of its kind in form and productiveness, is to be pulled up, and all malformed fruits on those that are left, are cut away. Then only the earliest clusters are allowed to ripen, those which set late are cut off, and the whole strength of the plant directed to ripening the first fruit that is set. Take squashes for another example, and it is the same with melons, cucumbers, and all of the family. Few who have gardens content themselves with a single variety of squash. There are few plants so likely to mix, through the agency of bees. We know of a case in which the Hubbard Squash had been grown in the same garden with other squashes for several years, and the seed was yearly saved and planted. At the time we saw the squashes, they were mostly yellow, and instead of the pointed end, so characteristic of the Hubbard, many of them had the broad, flat, blossom end belonging to other kinds; indeed there was not a typical Hubbard in the lot. If seeds are to be raised, that should be the leading object for which the plants are grown. It is poor economy to sow seeds of doubtful purity, in order to avoid a small outlay for those of good quality.

Green-House and Window Plants.

All repairs, painting, etc., should be done to the green-house in good season. If plants are kept in the green-house, give all needed shade and watering.... Plants outside, whether from the green-house or the window-garden, should have proper care, shade the pots from the hot sun by placing boards against them; give water freely, repot, if an inspection of the ball of earth shows that they need it; turn the pots occasionally to break off any roots that have run through the hole in the bottom of the pot.... Insects often do much mischief to plants in pots, and must be removed.... Make cuttings of plants of which a fresh stock is required.

The Need of the West.

The West needs more live-stock. That those States and Territories which grow an abundance of natural pasturage for twice the stock they now have, are in need of more animals, is evident. But that those States in which the range is restricted are in need of more stock, can be demonstrated on the basis of their over-production of corn. While all the States of the West produce more corn than is consumed at home, only Kansas and Nebraska produce a large surplus for export; and we shall consider these only, although the conclusion reached will apply to other States with a force proportionate to their surplus. In 1883, Kansas produced 172,800,900 bushels of corn, of which amount 77,760,405 bushels, or 45 per cent, was retained for home consumption, while 95,040,495 bushels, 55 per cent of the entire crop, were exported. In the same year, Nebraska produced 101,272,900 bushels; of this, 59,551,551 bushels, 59 per cent, of the whole crop, were retained for home consumption, while 41,521,349 bushels, 41 per cent, of the crop were exported. Thus, of their crops for 1883, these two States consumed at home, 137,514,956 bushels, and exported, 136,561,844 bushels, practically half the crop. During this time, the railroad charges for corn from Kansas City to Chicago, were, by the car-load, 20 cents per one hundred pounds. At this rate, the cost of transporting the surplus corn of Kansas, from Kansas City to Chicago, would be \$10,644,535.40. During the same time, the railroad charges for transporting corn from Omaha to Chicago, were 25 cents per hundred pounds; at this rate, to transport the Nebraska surplus from Omaha to Chicago, cost \$5,813,408.86. The cost of transporting the surplus of both States to Chicago, was \$16,457,944.26. If this surplus had been reduced to pork, at the rate of ten pounds of pork to each bushel of corn, the product would have been, 1,365,648,440 pounds—950,404,950 pounds from Kansas, and 415,243,490 pounds from Nebraska. During the period of exportation, the railroad charges for transporting live hogs from Kansas City to Chicago, were \$42.50 per car-load of 20,000 pounds. At this rate, it would have cost \$2,019,600 to transport from Kansas City to Chicago, the Kansas surplus of corn, if it had been in the shape of pork. During the same period, the railroad charges for transporting live hogs from Omaha to Chicago, were \$70 per car-load. At this rate, to have transported from Omaha to Chicago, the Nebraska surplus in the shape of live hogs, would have cost \$1,453,340. The cost for the two States, would have been, \$3,472,940, a saving on freight alone, by transforming the corn into live hogs, of \$12,985,004.26, or almost 400 per cent. But to this, it may be objected that all this surplus did not reach so far east as Chicago. This is true; but the cost of transporting the corn from the various points in these two States to Kansas City or Omaha, would far more than compensate for this, as the transportation tariffs are heavy for short distances on branch roads.

Some of this corn went east of Chicago. Let us calculate what would be saved on the transportation from Chicago to New York, of one million bushels of corn, by changing it into live hogs. The railroad charges last year for transporting grain from Chicago to New York, were 30 cents per one hundred pounds; at this rate, the cost of transporting 1,000,000 bushels of corn, would be \$168,000. Transformed into pork, the transportation would cost 35 cents per hundred pounds, or for the million bushels in this shape, \$35,000; a saving of nearly 400 per cent.

These figures show plainly why that portion of the West which produces a surplus of corn above home consumption, needs more live-stock. The saving in transportation alone, when the corn is converted into live hogs and shipped in such form, aggregates an enormous amount, and if it were put into the form of beef or mutton, the saving would be substantially the same. Cattle are shipped from Omaha or Kansas City to Chicago, at a less rate than hogs, and sheep at the same.

But every bushel of corn shipped, represents so much fertility taken from the soil, leaving nothing to replace it. The West needs live-stock to maintain the fertility of its land. Without stock, the more intensive farming, the larger the crops, and the more rapidly will the land be impoverished. So long as the West is without live-stock to consume its productions at home, just so long will the impoverishing of the soil continue. On the other hand, the fertility of the soil may be maintained by feeding produce to farm animals, saving and applying their manure, liquid and solid, and reinforcing this with a little green manuring. The value of this animal manure, which would represent just so much gain to the farmer, can not be accurately calculated. But as we have made our former calculations upon the basis of a production of ten pounds of live pork from each bushel of corn, we would have 46 pounds of manure for each bushel fed, estimating a bushel of shelled corn at 56 pounds. This would have given Kansas and Nebraska 3,139,500 tons of animal manure, if the surplus corn of last year's crop had been fed to hogs. These States need all the fertilizing

materials at their command to keep up the land, hence they need live-stock to consume surplus production.

Passing over with only a mention the profitable work offered by stock-raising, at a season when grain demands no attention, we wish to notice another particular wherein more stock would be advantageous to these States. One travelling through these States, is struck with the lack of cribs and granaries. As a result, the farmers are compelled to sell their surplus grain as soon as it is harvested. The consequent rush of grain to market at certain seasons of the year, brings prices down to low figures, which the necessities of the farmers compel them to accept. If the grain was fed to stock, it, so-to-speak, could be held for a higher price.

Animal Ailments.

DR. D. D. SLADE.

SWINE PLAGUE.—E. T. Beall, Liberty, Va.—The disease which killed the three fine hogs that had a range of seventy-five acres and plenty of running spring water, was undoubtedly, from the description of symptoms, the swine plague, although this disease may have its seat in almost any organ, its presence in the lungs to a greater or less extent, is now considered as characteristic. Treatment in our present knowledge of the affection is not to be considered—the disease is highly contagious. Warts may be safely destroyed by tying a strong thread about their necks, or by cutting them off with scissors, and touching the surface with lunar caustic or blue stone.

MANGE IN DOG.—Mrs. H. A. Fink, Westerly, R. I.—The Gordon setter undoubtedly has skin acari, or animal parasites, which burrow in the tissues, and cause great, and uncontrollable itching, as well as scabs and sores upon the surface. Oil well the surface affected, and then with soapsuds (castile soap is preferable) remove the hardened crusts. Apply once a day, a small quantity of sulphur ointment, well rubbed into all the parts of the skin where the eruption has made its appearance.

NAVICULAR JOINT DISEASE—RINGBONE—THICKENED SINEWS.—C. L. Linsley, Bellows Falls, Vt.—In the very early stages of the Navicular disease, rest at pasture may give the parts a chance to recover. A wet pasture free from stones is preferable. Remove the shoes—or the animal may be kept standing in wet clay in the stall during the day time, and removed to a dry stall at night. If the disease has gone on to ulceration, the cure is longer and more uncertain. A seton through the frog, which must be passed by a competent person, is sometimes of service. If the lameness continues after a month from the removal of the seton, this treatment at least, is useless. The seton should remain in place for four or five weeks. In the treatment of Ringbone, rest is often essential in the early stages—allay the inflammation by soothing measures, such as fomentation of the parts, and then blister, when soreness and heat have lessened. When this disease is in the fore leg—the heel comes to the ground first, and a thin-heeled bar-shoe must be put on. If, on the contrary, the animal walks on his toe, as when Ringbone occupies the hind limbs, a high-heeled shoe will enable him to travel more comfortably. Thickened sinews in the first stages, may be benefited by rest at pasture, and by blistering occasionally. The disease is due to strains and over exertion, and very rarely do the parts assume their original, normal condition, and when benefited by treatment, are prone to return to their unnatural state when the animal is put to work.

BLACK LEG IN CATTLE.—A correspondent from New Mexico, advocates the removal of the tail and ears in cases of real or supposed Black Leg in cattle. Whereas, in the very early stages, bleeding, properly performed, may be advisable, it seems to us a rather heroic, if not barbarous treatment to subject every suspected animal to the above operation. At any rate, this proceeding would not be satisfactory to humane people.

SWOLLEN HEAD IN PIG.—G. M. Wertz, Johnstown, Pa., has a pig six months old, with face and head swollen to an extreme extent for at least three weeks. The pig is of common stock, has not refused food, but eats indifferently. This condition is evidently due to a scrofulous disease of the bones, which become infiltrated with a jelly-like substance. In all probability the disease will prove fatal, if the diagnosis is correct. No treatment is advisable, as the animal thus diseased is unfit for breeding or for food.

SPRUNG KNEES IN HORSES.—J. H. Levy, Franklinsville, Gloucester Co., New Jersey.—The condition known as Sprung Knees, is indicative of over exertion, and of an undue amount of work which has been thrown upon the ligaments of the fore-limbs. It is usually impossible to fix upon any one portion as being at fault more than another, where the entire limb participates in this abnormal state. Undoubtedly there is an hereditary tendency in some horses to take on this peculiar condition. No treatment can be of any avail, and beyond the un-

sightly appearance caused by the trouble, the animal is not, as a rule, materially injured for moderate work.

UMBILICAL HERNIA.—W. H. Allen, Calais, Maine. The bunch formed on the belly or navel is undoubtedly a rupture, a condition not uncommon in this region of the body in young animals. A correct diagnosis may be obtained by gently kneading the contents and at the same time endeavoring to push them up into the abdomen. If they return with a gurgling sound, it is a rupture. To keep the intestines in place, make a soft pad of folded cloth or any similar material, and attach it with sufficient pressure to a band passing round the body and fastened to a similar one running round the neck. Blistering the parts repeatedly is sometimes effectual, when the rupture is not large, and not of long standing. The bunch should by no means be punctured.

FOUNDERED HORSE.—"Cincinnati," Cincinnati, Ohio. The term founder is used very indefinitely, and conveys ideas that are apt to be very confused. The disease to which the word should be restricted consists of inflammation of the sensitive portions of the feet—which inflammation may be either recent or long standing. In the early stages of the affection, every effort possible must be made to subdue the inflammation, and to restore the parts to their healthy condition. For this purpose large poultices are to be applied to the feet, and the animal encouraged to lie down. In order to prevent congestion, it is advisable in this early stage to walk the horse without shoes, on soft plowed ground. Where excessive tenderness and inflammation have set in, exercise is out of question. A mild laxative (not purging), should be administered—one-half an ounce of Aloe is most appropriate, followed by injections of water into the rectum if necessary. In very severe cases, bleeding from the coronet may be advisable. If the inflammation persists after two or three weeks, a condition known as chronic Laminitis follows, accompanied by various changes in the internal structure of the hoof. For this long rest at pasture, blistering, and the application of a thin heeled bar-shoe are the appropriate remedies. In the worse cases complete restoration of the foot to its healthy condition cannot be expected. The convexity of the sole must be counteracted by the use of a thick, broad, webbed bar-shoe, and the animal placed in the wettest pasture possible. Shorten the toes and lower the heels if necessary. The animal may be used for slow farm work on soft ground a long time before he is fit for use at a quick pace upon hard roads.

TUMOR ON THE NECK OF OX.—E. J. Burr, Royal, Nebraska. The tumor may be best removed by extirpation, which should be done by a surgeon. It is undoubtedly simple in its nature, and may be removed by the knife without difficulty. If this is not possible, on account of the want of an experienced hand to perform the operation, try the effect of some stimulating ointment, such as the Iodine, which may be procured of any apothecary.

NERVOUS IRRITATION OF SKIN OF HORSE.—Jno. D. Pryon, Windfield, Kansas. The animal is suffering from Neurosis, or nervous irritation of the skin, which shows itself more particularly under the influence of hot weather, and is accompanied by pimples or vesicles, which become broken by rubbing. For treatment a complete change of diet is advisable, which, if in the stable, should be restricted; a change to pasture may be advantageous. Give gentle laxatives, with green food, wash the skin daily with soapsuds moderately strong. If no improvement, after a few weeks of trial, give bicarbonate of soda in the drink, half an ounce per day. The chief objects in the treatment are to remove any offending substances from the intestines, keeping them somewhat relaxed, and to change the animal's entire diet.

A BRIGHT SPOT IN A DINGY STREET.—Business took us, a few days ago, through one of those streets in New York City that one never visits unless from necessity. It is a crowded thoroughfare where more than one half of the shops are beer saloons and gin mills, and the others devoted to junk dealing and small trades. The upper part of the houses are crowded tenements. One of the dingiest of the buildings retained as a relic of former prosperity a narrow iron balcony, running across the whole building, at the windows of the second floor. This balcony was occupied by a box for its whole length, perhaps twelve feet long and about a foot wide and high. The box had been filled with soil, upon which grass seed had been sown, and there were three young trees of the Ailanthus, one in the middle and one at each end, forming, with the fresh green of the grass and the tropical foliage of the Ailanthus, as pretty a piece of "sub-tropical gardening" as can be imagined. This green spot brightened up the street for a long distance, and afforded the eye a refreshing rest, after gazing upon the displays of the second-hand clothing stores. Whoever instituted that window box is a public benefactor, and we thank him for the refreshing glimpse of balcony-gardening he afforded us.

Boston Brown Bread.—Several house-keepers have asked for a recipe for Boston Brown Bread. The term "Boston," is applied in all New England cities to bread baked in conical iron pans. We give the recipe which has long been in use in the family of the writer. Inasmuch as the recipe came from Boston, the bread may be called Boston Brown Bread. At any rate, if there is any better bread than that made by this recipe, we should like to know how to make it: Indian meal, two heaping cupfuls; rye meal, two heaping cupfuls; milk, three cupfuls, scant; soda, one teaspoonful; salt, one teaspoonful; molasses, three-fourths of a cupful. Mix, and steam for five hours.

Self-Opening Gates.—Every few weeks some one, all the way from Maine to Oregon, asks, "which is the best self-opening gate?" Those who manufacture such gates should advertise them. We some years ago lived in a neighborhood where such gates were in frequent use. From our experience there, we would not have such a gate, if it were put up without cost. Those that open by the striking of a wheel of the vehicle against a lever, cannot endure the shock of repeated blows, and soon give out. In winter they are so clogged with snow and ice, as to be useless. But why have a self-opening, or any other gate? A gate is only of use to keep out stray animals. In all but newly settled localities, the law against allowing cattle to run at large, should make gates of any kind a useless expense.

The New Orleans Exhibition.—Though the full title reads, "The World's Industrial and Cotton Centennial Exposition," it will not be so exclusively confined to Cotton and Industrial matters, as generally understood, as its title might suggest. Abundant space is provided, and liberal prizes offered for horticultural and pomological exhibits of all kinds, not only from our own growers, but those of Europe also. Mr. P. J. Berckmans, President of the Georgia Horticultural Society, and the leading pomologist of the Southern States, left for Europe last month, as a special Commissioner to interest European pomologists and horticulturists in the New Orleans Fair. A better selection for this commission could not have been made, and we commend Mr. Berckmans and his object to European cultivators.

Stocks for the Cherry.—J. R. Osborne, Bethany, N. C. Cherries are separated into two classes: those with heart-shaped fruit, the Hearts and Bigarreos, and those with round fruit, the Dukes and Morellos. The Mazzard, which you probably know as the small black cherry, makes the best stock for the Heart and Bigarrean varieties, while the sour red or pie cherry, is used for the round-fruited kinds. To preserve the seeds, allow the fruit to be thoroughly ripened; it is placed in a tub with water, and by a gentle pounding, the pulp is removed and washed off. The stones are then spread on boards to dry; afterwards they are mixed with sand, which is very slightly moist, and kept as cool as possible. It will probably be better, in North Carolina, to plant the stones in the fall, as even in Northern localities, it is difficult to keep them from sprouting before the soil is ready in spring.

How to Keep Eggs.—Eggs may be kept from late summer or autumn well into the winter, or even spring, but it is next to impossible to deceive the dealers, and very few consumers are deceived by them. "Lined eggs" have their regular market quotations throughout the winter, and usually sell at one quarter to one sixth less than fresh ones. They are lined by packing them into barrels or smaller casks, point down, and pouring on them the water from lime slacked with brine, to a thin milky consistency, using just enough to cover the eggs, so that the next layer can be conveniently placed upon these, and then more lime-water added. When the cask is full, the eggs must be covered with a cloth and this spread over thickly with the pasty lime, then, if the water evaporates, or if the pasty lime cakes and cracks, more water must be added. It is essential that the eggs should be perfectly fresh, clean, and sweet when packed, or the whole lot will go wrong. There is probably no better way of keeping eggs for market than this. For family use they may be greased, dipped in hot paraffine wax, scalded, and perhaps preserved in other ways. The lime and salt liquid imparts no flavor, and does not deface the egg, which, when offered for sale, has a slight chalky appearance foreign to and distinguishes it from a fresh laid egg.

Chat with Readers.

Is Sulphur a Good Fertilizer for Fruit Trees? asks *S. Deal*, Seneca Falls, N. Y. Sulphur is of no value in supplying plant food, though it may be of use in destroying and preventing the growth of fungi, and thus benefit the trees by keeping off their enemies.

"Old Subscriber," Basking Ridge, N. J., asks us for reference to a back number, and also where a market can be found for old coins. Had the name been given, we could have referred the writer by letter to September, 1879, and also given the name of a dealer in coins. It is against our rules to advertise coin dealers and others in these columns.

Lime or Ashes with Guano, etc.—*J. C. Norris*, Huntsville Conn. When lime or ashes is mixed with guano, hen manure or other fertilizers containing ammonia, or readily yielding it, there is a loss of a valuable constituent. If the soil needs lime or ashes, sow the other fertilizer first, and when that is well incorporated with the soil, the lime or ashes may be applied without loss.

Removing Varnish.—*M. F. Carlton*, Chicot Co., Ark., asks how to remove varnish without the use of sand paper. Benzine will dissolve varnish readily, but as we are not informed what kind of a surface it is upon, it would be well to make sure that benzine will not injure the rest of the work. In using benzine, be cautious and keep away from fire or flame; the vapor mixed with air will explode.

Crude Petroleum and Kerosene.—*W. F. Brown*, Columbus, O., asks, if coal oil, or kerosene "is not as valuable for preserving fence posts as crude petroleum?"—By no means. Kerosene is a light volatile oil, which in time would completely evaporate from the wood. Crude petroleum, on the other hand, contains the non-volatile and preservative matter, which will remain in the wood.

Chestnuts for Planting.—*J. B. Govey*, Dallas Co., Iowa, asks us, "where can I get chestnuts for planting?" Chestnuts for seed should be procured in autumn, at the time they are ripe, mixed with an equal bulk of sand, and kept until spring in a cool place. There will be less danger from freezing than from heating. We have sent you by mail the addresses of several dealers, who may be able to supply chestnuts that have been properly kept for planting.

Lightning Rods.—In a former article upon Lightning Rods it was stated, that the lengths might be joined by welding. Several have written to ask, if round rods can not be united by means of screw couplings in the same manner as gas-pipes are joined. Certainly, a screw coupling will answer; we mentioned welding, as the average country blacksmith can more readily join the rods in this way than in any other.

Pinching Tomato Vines.—*C. H. Tufts*, Wakefield, Mass. If tomato vines are allowed to bear all they will, the frost will arrest their growth with a heavy load of green fruit, from that just set, up to that nearly ripe. Had all the clusters of flowers and young fruit been cut away, except that which could have ripened before frost came, the remaining fruit would have been larger, finer, and probably somewhat earlier, though the gain would have been more in quality than in time of maturity.

Screen for a Carp Pond.—*S. Schwartz*, Wynant, O., has a carp-pond, and would like to know how to prevent the young fish from escaping when water runs out of the funnel-shaped waste-way. We infer that the waste-way is built of wood, and it can be readily made safe by the use of a screen of wire netting, which can be had of any desirable fineness. As floating leaves, sticks, and other rubbish may clog this screen, it will be well to place in front of the netting, and a few inches from it, a screen of wooden slats, to arrest the floating matter before it reaches the wire.

Trouble with Currant Bushes.—*"Samuel Miller,"* Phillipsburg, Pa., sends us stems of a currant bush, which look as if they had been sprinkled with whitewash. These spots are thin white scales, under which, if examined early in the season, will be found minute red eggs. The same scale is not rare upon pear trees, but we do not recollect to have seen it on the currant before. It is known as Harris's Bark Louse. We should try the emulsion of kerosene, mentioned in the March *American Agriculturist*, page 114, applying it freely.

Almonds and Pecan Nuts.—*R. M. Gard*, Moultrie, Fla. The almond can usually be cultivated wherever the peach will grow, and is propagated in the same manner, i. e., choice varieties are budded upon seedling almonds. It is also budded upon the peach and plum. As the Pecan grows abundantly in Texas, in a similar latitude to yours, so far as climate is concerned, it would no doubt flourish in Florida. It is said to be, like other hickories, very slow in coming into bearing from the seed. Trees of both Almonds and the Pecan, may be had at the large nurseries.

Time to Start Cuttings.—*Miss H. Gibson*, Petersburg, Pa., asks us the proper time to start cuttings of flowers for winter blooming. As the kinds of plants are not mentioned, we can only give a general answer. Plants that grow slowly should have their cuttings made this month; for rapid growers, like verbenas, September will be early enough. The two methods mentioned in an article on "Cuttings from Unripe Wood," will either of them answer for ordinary bedding plants, though the "Saucer Method" will succeed better after the hottest days are over.

A Lot Overrun With Plantain.—In April last (page 154), we made use of the complaint of a subscriber in New Lisbon, N. Y., that he had a ten-acre lot "covered"

with Plantain, as a text for an article on weeds. Now, Mr. F. H. Brinker, Medina Co., Ohio, suggests with reference to this lot, that seeding it down to Timothy grass, will kill out the Plantain. Otherwise, he suggests making use of the lot as a pasture for a few years. He says that in Ohio, both cows and sheep are fond of the Plantain when it is young and tender, and they keep it so well subdued, that it does not go to seed. Sheep are excellent weed exterminators.

Troubled with Wasps.—*J. R. Francis*, Fall River, Mass., having altered over an old house, is much troubled by wasps, which enter the rooms and are very annoying. Probably a search would discover the wasps' nests, which are sometimes built under the eaves, or in some part of the garret. When the nests are discovered it should not be difficult to destroy them. If the place admits of it, fumigation with sulphur fumes might be tried. Fumigation by burning Insect Powder (Pyrethrum), is said to kill mosquitos, and it would be worth while to give it a trial with the wasps—always avoiding the business end of the insect.

Railroad Horticulture.—The surrounding of the signal houses and other buildings of some of the railroads running out of N. Y. City, are decorated and kept in a manner highly creditable to the workmen, and pleasing to the passengers who pass over the roads. What were formerly waste places, disfigured by rubbish, are now laid out in lawns and grass plots, in which are beds of showy flowers and plants with ornamental foliage. There is room upon most railroads for improvement of the grounds around the stations. Some railroads have this done by contract, while the horticultural adornments seen on others, are due to the good taste and enterprise of the employees.

Squash Bugs.—*"C. H. Blair,"* East Palmyra, N. Y., wishes to know "how to keep the bugs off of squash-vines, especially the Hubbard." By "bugs," we suppose that our correspondent refers to what is known as the Squash-bug, *Anasa* (formerly *Coreus*) *tristis*, that solemn-looking insect, belonging to the true bugs. It is readily recognized by the horrible stench it gives off when disturbed or crushed. The last of the month of June, or early in July, these insects leave the places in which they have hidden themselves during the winter, and seeking the squash-plants, lay their eggs on the under surface of the leaves. The only remedy is, to catch and kill the female insects, and to crush the eggs, always upon the underside of the leaves. These are the best methods of keeping these insects in subjection.

Glass Insulators for Lightning Rods.—We have frequently stated that the use of glass insulators upon lightning rods was a useless expense, because as soon as they are wet by the rain, they cease to insulate. W. E. Godding, Norfolk, Mass., describes a case occurring in his town, which would seem to be an exception to the statement that insulators were useless. A copper rod was fastened to the house by glass insulators, the lowest of which was broken off. The lightning descended the rod, and when it came to the broken insulator, left the rod and entered the house, following the floor timbers, tearing up the floor, and went out in the direction of the well, about twenty feet from the house. This shows nothing as to insulators, but indicates that the rod had not a proper earth termination. The lower end of the rod was in dry soil, and the lightning merely took the shortest road to a good conductor, the water in the well. The lower end of the rod, which is out of sight, is really the most important part of a lightning rod.

Gapes in Chickens and Turkeys.—*J. W. Bailey*, Bridgeport, West Va., sensibly asks, how to prevent as well as to cure gapes. Our domestic animals, especially poultry, would need very little medication were the causes of their diseases generally understood, and preventive measures adopted. Chickens and turkeys are attacked when from four weeks to six months old. The disease shows itself, as its name implies, by continuous gaping; the chicks are dull, and cough and sneeze. When dead, numerous small worms are found upon opening the wind-pipe. Damp quarters, unwholesome food, and especially impure drinking water, are regarded as promoting the disease, if not the cause of it. A small feather has the plume stripped from all but about half an inch from the smaller end of the shaft; this is dipped in spirits of turpentine, and passed into the wind-pipe through an opening to be seen back of the base of the tongue. The feather is turned around once or twice and removed. A share of the worms will come out with the quill, while others will be thrown out by the coughing caused by the turpentine. After the worms have been removed in this manner, the young birds should be kept in a warm coop from the damp earth, and be fed upon warm soft food.

Cabbages and Club-Foot, or Clumping.—*J. E. Overton*, Port Jefferson, N. Y., asks us if we have known cabbages to be raised upon the same ground two years in succession, without "clumping," and if potash salts or plaster would be of any use in preventing the trouble. There are lands on the New Jersey shore, upon which cabbages have been grown for twenty years or more in succession, and no club-root has appeared. Finding this soil to be filled with minute fragments of shells, Mr. Peter Henderson suspected that these acted as a preventive of the cabbage trouble. In order to ascertain if lime in any other form would act in the same manner, he applied bone-dust, at the rate of a ton to the acre, to land that would not bear two successive healthy crops of cabbages. This was done side by side with a plot highly manured with stable manure, and both were planted with cabbages. On the manured portion, the plants were badly injured, while on that to which bone was applied, not an injured plant was noticed. Experiments are needed to ascertain if a much smaller application of bone would not prevent the trouble, and if lime in the form of ground shells may not serve the same purpose.

French Farming.

France is one of the richest agricultural countries of Europe. Its two hundred and four thousand five hundred square miles of area, produce both temperate and sub-tropical crops. The olive, the mulberry, and the vine flourish in the south, and in the north and northwest (the most fertile

THE PROPRIETOR.

part of Europe), the wheat and beet-root are the staple crops. The latter is a most important product, as it is upon it that the sugar supply of the country mainly depends. Beet-root sugar first became known in France when the wars of the first Napoleon closed the Empire to importations from America. Its manufacture is now one of the great industries of the country.

Unlike England, France is a country of small proprietors. The great revolution wrested the vast estates from their hereditary owners, and threw them into the market. They were then broken up and purchased piecemeal, and though many large properties have been gathered together since then, their number is small compared with that of the individual farms. The result of this

though he may be a careful man, does not stint himself of necessities. He lives well, and he educates his children. In France matters are different.

Hard work and frugal fare are the rule with the French countryman. The "proprietor," as he is called, the master of the great farm, lording it over herds of fat cattle and fleecy sheep, does not pamper his body. On market days you see him at the village inn, admired and envied. He wears, as a holiday outfit, a clean blouse over his white shirt, with its tall collar, around which a satin tie is twisted; his pantaloons are of shiny broadcloth, his shoes of strong, fine leather, without a patch, and he carries a great silver-headed cane. He takes double as many lumps of sugar in his coffee as another man, talks in a blustering voice, and is universally respected and feared. These proprietors form a very rich and powerful class, but they are often ignorant to an incredible degree. They grow rich simply because the people beneath them are more ignorant than themselves.

To the misery of the poor in the French agricultural districts, no mere description can do justice. Like the condition of the English agricultural laborer, their's is one of black, hopeless privation. There are sections in which meat is an unknown article of diet to them. At best they get a scrap of it, and that of the cheapest kind, once a week. Bread of the poorest quality, and potatoes, form their staples of diet. The bread is generally baked in batches to last several weeks, and it is eaten even when bitter with mould. In the mountain districts of France, the agricultural poor supply the place of potatoes with a fungus picked in the woods, which is of a kind too coarse for market.

Thousands of the small farmers, however, live from choice, quite as poorly as their laborers. The miserly instinct is a characteristic of some of the people. They save at the expense of their bodies and their minds. All that they raise in a condition fit to eat is sold; the rest they live on. The agricultural districts of France are very wealthy in money hoarded away by people whom one would not suspect of being anything but beggars, if they were encountered on the high-road. The holiday suit often lasts the farmer a lifetime. He only wears it on occasions of show, and is not ashamed of his working clothes. The types of country life in France are probably distinct from those of any other country in the world. In some sections, the

plow. With small farms and cheap labor, such a method is possible, but it would make France a new country for the farmer, if it was plowed up from end to end like one of our great farms. American tools find little favor with the French farmer as yet. There are a few in use, and they are apparently regarded as curiosities. We once passed a group of fifty people gathered at a roadside in Normandy, to watch the working of an American plow.

A COMPLAINT TO THE LANDLORD.

French farmers are very litigious. They go to law at the slightest pretext—for a bundle of fagots, or a few bunches of grapes. This has doubtless given existence to the *garde champêtre*, a sort of rural policeman, whose duty it is to keep guard over the fields, and watch for trespassers, and who is constantly called upon to render official service to the farmers. Politically the farmers form a powerful and important class, and they are canvassed at every election by rival agents from the cities. As a rule, they are conservative. All they want of a government, is for it to give them peace and a good market. Given these, they are satisfied to be ruled as the government chooses.

In France, as in England, the first lessons of

EVENING ON THE MARNE. — Drawn and Engraved for the American Agriculturist.

condition of affairs, is that while in England wealth centres in the manufacturing districts, and the great cities, in France it is generally diffused over the whole country. In England the farmer pays heavy taxes and heavy rent. In France, he pays heavy taxes but no rent. He saves money, and there are few farmers indeed, who are not small capitalists. The extremely frugal habits of the agricultural people of France, aid in bringing about this result. In England, as in America, the farmer,

men and women dress according to their employments, so that you can distinguish between the field and the stable laborer, the dairy women, and the house servant at sight.

The various implements now in use on the finest farms in France, would be considered old-fashioned across the channel. In the best sections, the plow is yet little better than that which the Egyptian uses to scratch the soil. On very many farms, the spade and hoe are made to do duty for the

childhood are labor. The babies are made scarecrows of, and set to watching the geese; children of larger growth drive the lean swine, which look like dogs in their meagreness, and drudge in the barn-yards and the fields. The writer once had a boy pointed out to him as the brightest lad in a little French village. When asked in what his brightness consisted, the proud parent pointed out a garden patch next to the house, and said: "He raises that, filled every inch, with peas every year."

FARM LIFE IN FRANCE.

Drawn and Engraved for the American Agriculturist.

Sheep Raising in the Northwest.

There is no scope in the territories of Dakota, Montana, Wyoming, and Idaho, for the profitable keeping of very large flocks of sheep as are kept in New Mexico and Southern California, or in Western Kansas and Texas. Five thousand head is as many as it is wise to keep in a single flock, but at the same time there is nothing to prevent a man who has successfully built up a flock of this number to divide it, if he can find a suitable location within convenient distance, and where he can give his personal attention and superintendence at proper times, and so manage two flocks of this size. Experience has proved the wisdom of making a sure thing of one manageable flock, rather than to try to keep two and fail with both. The old proverb "between two stools one comes to the ground," is applicable to this business. The general average of the flocks through this region is from two thousand to six thousand, and the lower limit is far more frequent than the higher one. A thousand sheep is the usual starting point, and is a safe one. To begin with such a flock, a capital of five thousand dollars should be in hand. If one has more, it would be well to loan the remainder at good interest and risk only this amount. The expenditures will be as follows:

COST OF STARTING A RANCH.—One thousand sheep, at \$2, \$2,000; twenty pure Merino rams, \$500; sheds and buildings, \$500; expenses, first year, for two herders and other help, \$1,000; horses, wagon, etc., \$500; reserve fund \$500. The probable income and increase is three thousand five hundred pounds of wool, \$700; and seven hundred lambs. The fleeces of the improved lambs will be worth fifty per cent more than those of the ewes, including the increase in weight and the higher market value, and the second year, the wool will at least pay all expenses, as no more labor for herding will be required for two thousand than for one thousand sheep. The cost of bedding and feeding a small flock will amount to about seventy cents per head per year; for flocks of two thousand and over, the cost will be reduced to fifty cents or even less under favorable circumstances, and when the owner takes his share of the work. The Colorado and Oregon sheep require less feeding in the winter than Iowa sheep, as they are hardier and better "rustlers," that is, better able to withstand the storms of winter.

In Wyoming the sheep are generally Mexicans crossed with Merino or Cotswolds and brought from Colorado. In Idaho the flocks are usually brought across from Oregon, and are much like the Mexican, small and light, but strong and hardy. In Montana the sheep are of better quality, having more Merino blood in them, and many well-bred grades from Michigan and Minnesota are brought out on the railroad. Powder River; the Judith basin on Grave-yard creek; the Gallatin Valley around and south of Bozeman; and the Missouri Valley and its tributary valleys past Helena and down to Fort Benton, are especially desirable localities for sheep in Montana. Further west is the mountain region in which good localities may be found in abundance. Last winter, snow first covered the ground about February 1st, and remained until the 20th, when the warm south wind, known as the "chinook," melted it and left the ground bare in a day. The losses of old sheep are scarcely worth counting; among the young ones, two per cent will cover all, and when the best care is exercised, the losses by death may not exceed five in a thousand, and those from accidents. The most frequent losses are caused by a native grass which bears exceedingly sharp awns or beards, and called popularly "needle grass." Botanically it is *Stipa spartea*. The long grain, or seed, of this grass is inclosed in a firm leathery chaff, which, at its upper end, bears a slender twisted "awn," or bristle, five or six inches long. These awns twist and untwist, as the weather is dry or wet, and the plant, on this account, is called "weather grass." These grains, with the long awn at one end, and the hard, sharp point at the other, drop from the

plant very readily, and catch in the wool. The lower end of the chaff is furnished with a hard and very sharp point (botanically called *callus*), which readily penetrates the flesh. Being furnished with stiff hairs, all pointing in one direction, this callus, and the attached chaff and included grain, work into the flesh with every motion of the animal. The sharp point penetrates the skin and works into the flesh and even into the intestines. They also are found in the mouth, or if swallowed penetrate the stomach, and cause death. On this account it is necessary to examine the sheep frequently and extract the "needles" from the wool and skin. The remedy, or rather the method of prevention, used by shepherds, is to make a fire break; which is a strip of plowed land around a portion of the pasture, and not permitting the fire to run until June when the needle grass having started into growth, the fire is started and the dead grass burned off; along with which the young needle grass is killed for that year.

Another frequent trouble through most of this region is from the dust, which is alkaline and irritates the lungs and nasal passages, causing a cough and discharge from the nostrils. This of course is a natural consequence of the character of the soil, and cannot be overcome excepting by avoiding pastures of this kind, or by providing other feed for the flocks at the seasons when the trouble mostly prevails, which is in late fall and winter.

Wire Worms—True and False.

When a correspondent writes that the "wire-worms" are injuring his crops, and asks how he shall prevent them, we are not certain as to what insect he refers. There are several very unlike insects, popularly known as wire-worms. The true wire-worms have but six legs, while the millipedes

CHICK BEETLES AND WIRE WORMS.

or false wire-worms, have very many. The true wire-worms are the larvæ or grubs of a beetle, and in time appear as winged insects, while the false wire-worms have the same general appearance in their larval and perfect state. The perfect insect of the wire-worms is a beetle, of which there are numerous species, varying greatly in size, but of the general form shown in the engraving. When laid upon their backs, these beetles are able, by means of a sudden jerk or spring, to throw themselves up for several inches into the air, and usually alight feet downwards. On account of this peculiarity they are known as snap-beetles, spring-bugs, skip-jacks, etc. They are usually brownish in color, though some are covered with short, gray hairs, and appear ash-colored. The eggs are laid near the roots of a plant, either upon the surface of the ground or just below it, and the young grub feeds upon various small roots, and sometimes enter the stems in search of food. The worms live for a long time in the ground, some of them it is said, as many as five years. As they travel through the soil, feeding upon the young roots, they do much injury. When they have attained their full size, the worms go deeper into the soil, form an earthen case, from which, in a few weeks, the perfect beetle escapes, and makes its way to the surface. As a general thing there is not much to be hoped from direct applications to destroy the wire-worms.

In England, the use of soot, salt, guano, and other fertilizers applied for the benefit of the crops, have been thought to diminish the number of wire-worms. In gardens, the worms may be trapped by means of pieces of carrot or potatoes; each piece is fixed to a stick a few inches long, and buried just below the surface of the soil. The sticks, which project above the surface, allow the pieces to be readily found; they are taken up every other day, and the worms killed. Keeping land in fallow is recommended, to starve out the worms, and the burning of all rubbish may destroy some. Probably the greatest help will be from the small birds, which will destroy the beetles in great numbers.

Shade Trees on the Farm.

A few well-formed trees along the fence rows, and even scattered here and there in the open fields, add greatly to the appearance and value of a farm. Cattle, sheep, and other farm animals, suffer greatly from the hot sun when confined in a shadeless pasture in midsummer. They will seek the slight protection from the broiling sun a fence may afford, or stand huddled together for hours, with their heads shaded by each other, in a most unhealthful manner. Animals thus exposed do not give the best returns to their owners, and for this reason, if not for comfort's sake, they should be provided with shade. Some farmers object to trees in the pasture, because their shade is too inviting, and keeps the live-stock from feeding. Farm animals need not graze all the time, and with good pasturage, can get all the grass they need in the cool portions of the day, between which they should have refreshing shade for chewing the cud of contentment. Men are not the only creatures that may be sun-struck; cows unduly exposed to heat, frequently become sick, quickly fall off in milk, and may require weeks of expensive nursing to bring them back to good health. Trees are an obstruction to the cultivation of a field, and occupy the soil for several feet around them, to the exclusion of grain or other crops, and therefore it is best to plant most of the trees along the line of boundary fences. The tired laborer is thankful for a few minutes of shade and rest, and doubtless will do more work by taking an occasional "breathing spell" under a tree. A tree in midfield may be a chestnut or hickory, and make good returns for the space it occupies in nuts, as well as refreshing shade. In many fields there is a low place with a spring or a small running stream, and is well-fitted for a group of trees. In short, any part of a field not suited to cultivation, may profitably grow a few trees, thus affording a retreat for the live-stock from the midday sun, and driving storms. If the pasture has no shade trees, it will pay to provide a temporary shelter. Four strong posts with forks at the top, may support two poles; across these lay smaller poles for rafters. The top may be covered with straw, swale hay, or, if more convenient, brush may be cut and laid upon the skeleton roof.

The Blackberry in Summer.

A blackberry bush, left to itself, becomes a straggling nuisance, catching the clothing, and being in the way generally. The novice should bear in mind that the bush which grows this summer will bear fruit next year, while the bush which has given fruit this season, is of no further use, and is to be cut away. The bush to give fruit next year should be formed this year. The blackberry produces suckers abundantly; only those needed to form bushes for next year's fruiting should be allowed to grow; the rest are to be cut up as if they were weeds. When a bush reaches the height of four, or at most five feet, stop it; that is, break off its growing end. This will cause side shoots to start along the stem, and when these are eighteen inches long for the lower ones, and a foot long near the top, stop these also, by pinching off the ends. A blackberry thus treated will be a neat, compact bush, and will not only produce finer fruit, than if left to itself, but can be approached without fear of tearing the clothing and scratching the skin.

An \$800 Barn.

R. L. HARRISON.

The barn, shown in figures 1 to 7, is placed on sloping ground, thus saving much excavation, and giving an easy entrance to the cellar. This brings the rear door of the granary just high enough for passing out bags of grain, etc., to a wagon. All

the feed room for unloading hay, etc. A hay-fork with railway is used, shown at *h*, figure 7. Hay is hoisted through the uncovered space *d, e, f, g*, figure 6, and with the hay-fork is carried back where wanted. The hay can easily be thrown into the feed room. The mow holds thirty to forty tons. The rafters are supported by four by four uprights, placed ten feet apart, and extending from the

The cost may be reduced by using timber less good, especially flooring and upright plank strips, instead of weather boarding or siding, and by using nine-inch brick walls and pillars under the front part where there is no cellar. In this way the cost might be reduced to six hundred or six hundred and fifty dollars. This barn has been in use several years, and has proved itself most con-

Fig. 1.—FRONT ELEVATION.

Fig. 2.—SIDE ELEVATION.

Fig. 3.—REAR ELEVATION.

brick walls are twelve inches thick, except the two parallel walls, which are nine inches. The front wall is built two feet below the sills, and one and one-half foot below the surface of the ground. The cellar walls are seven feet below the sills, and one foot below the surface in the rear. All studs, joists, and rafters, are two feet from centre to centre; the sills are framed together, and the studs are mortised into sills at both top and bottom. The corner and door-posts are four by six inches, and the former well braced with same sized timbers. All floors, except the stable, are dressed tongued and grooved plank; that in the feed room being an

lower floor to a cap-board let into the rafters.

venient and comfortable to both man and beast. Being well made, it has needed no repairs.

Hungarian for Hay or Green Fodder.

A quick-growing plant is required for a second crop sown on land after oats, or early potatoes have been harvested. Hungarian grass is excellent for this purpose, and with a rich and mellow soil will be ready to cut in mid-summer, or soon after. If the conditions are most favorable, a heavy crop may be obtained in six weeks from sowing. Pre-

Fig. 6.—PLAN OF SECOND STORY.

inch and a quarter thick, and the balance seven-eighths inch thick. The latter is also used for all doors and windows. In figure 1, the centre doors are hung at the top with iron rollers and rails, sliding back on the inside. At *a, a*, figure 4, are foundations for pillars, used to support the floor above. The small door *d*, in figure 5, is used for ordinary passage from feed room to the granary, but the whole partition in rear of feed room, *a, b*, is hung on hinges (see figure 7, *s, s*), and when necessary may be hooked up to the joists above. This is very convenient in threshing, the straw passing out at the rear door. The feed room is used for threshing, being wide enough for a two-horse tread-power and separator, or a sweep-power or engine may be placed in the front yard. The room at the side of the granary, containing bins, is ceiled on all sides with wide, dressed, tongued and grooved plank, and all corners protected with twelve inch strips of tin. This, with a close-fitting, self-closing door at *k*, makes a rat and mouse-proof place for storing grain, etc. The bins hold about one thousand bushels. The stables have slightly sloping floors of two-inch plank. Wagons drive into

pare the soil as for oats, wheat, or other grains, and sow one bushel of seed per acre. It may be sown broadcast and harrowed in lightly. The Hungarian fodder has obtained a bad reputation in some localities, without deserving it, simply because the cutting was delayed too long. The crop should be harvested as soon as the head is well formed, and before the barbed awns become hard and dry. The fully ripened bristles irritate the stomachs and intestines of animals, especially those of horses, and have sometimes done injury.

If the crop is grown to help fill the hay-mow, it should be cut and cured in the same manner as Timothy or Red Top, when it makes a good hay. Hungarian grass is especially recommended as a late crop to be fed green, when the pastures are short and dry from close feeding and summer drouth. For this purpose it may be sown in strips weekly, from early June to the middle of July. By growing a few acres of this late crop after an early one, a farmer is able to carry an increased number of farm animals and keep them in good order. Bear in mind, that the conditions of success are a rich, deep, and mellow earth, and on

well worn soil this means a plenty of quick-acting manure, applied before the grass seed is sown.

There are various sorts of Millets, which are closely related to the Hungarian, and like it are good for a second crop for green or dry fodder.

A Saw Holder.

A device for holding a saw while being filed is shown in the engraving. It consists of two up-right pieces of wood *a*, cut V-shaped at the top and securely fastened to an out-of-the-way part of the

A HOLDER FOR A SAW.

work-bench or other place. The saw is set between two long wedges *b*, which are pushed down and firmly hold the saw. A saw cannot be well filed unless it is secured from movements of all kinds, and this simple method will accomplish the desired end at very little expense.

Summer Poultry Roosts.

The presence of a pair of fine cedar trees in our poultry yard, accidentally led us into the belief that poultry fares much better if allowed to roost out of doors at night in summer, instead of being confined in hot, stifling, and often ill-ventilated, and filthy houses. Our poultry manifested a disposition to roost in the cedars in summer. Some of the limbs of the trees were low, drooping nearly to the ground, so that the fowls, even large and heavy Brahmas, found no difficulty in getting up among the branches. They were out of the reach of the weasel and fox, and being so completely hidden from view by the foliage, it was not likely that any prowling owl, or passing biped inclined on theft would ever discover them in the seclusion.

The result exceeded our anticipations. Not only did our poultry lay better, and more regularly than ever before, but were healthier, their coat of feathers looked brighter and livelier, and they kept in better flesh than ever before at the same season. Close houses are a necessity in winter, but in summer it is doubtless best to give fowls much more liberty, and all the fresh, pure air at night that they need.

Pulling Stumps.

Stumps are far more easily extracted after soaking rains have left the ground loose and yielding, than after the packing and baking of a season of drouth. For small stumps, especially on ground too wet and soft to admit the use of teams, a simple and effective arrangement may be used. A strong axle, say six inches square, is fitted to any stout pair of wheels, as those of a truck, to which a triangular lever is firmly bolted. It projects sixteen inches behind and sixteen feet in front, and is made of tough hard-wood, the pieces six inches square. To the end piece, which is mortised and securely bolted to the others, a chain with two stout hasps is attached. In using it, a broad plank is placed under each wheel to prevent sinking into the earth, and the wheels are blocked. The hooks are grappled into a root, and when raised as far as possible by depressing the lever it is blocked and a new hitch taken lower down. Two men can move the implement from stump to stump. The leverage would be nearly twelve to one, giving three thousand six hundred pounds power if the men weighed one hundred and fifty pounds each, and could both put their weight upon the extreme end of the lever—a power that would start small stumps.

The Turnip Crop.

Ruta Bagas are the most valuable of all turnips, and though we have known a good crop to be made not far from New York City, from seed sown as late as the middle of this month, it is better to sow in June. If from any cause one has omitted sowing turnips until now, he can either risk a late sowing of Ruta Bagas, or sow those which, like the Aberdeen, will mature in a shorter time. As the chances, in a good season, are in favor of making a fair crop of Ruta Bagas, if sown early this month, it will be good management to sow both these and the intermediate kinds, like the Aberdeen. The crop may be greatly hastened by a thorough preparation of the soil. The best cultivators sow on manured ridges. The land is thrown up into ridges thirty inches apart, the manure, the finer the better, is placed in the furrows, and then, using a double mould-board plow, the ridges are split and the soil thrown upon the manure, making new ridges over it. The seed is drilled in upon these ridges, using two pounds to the acre. If the black-fly, or beetle, is abundant, use more seed. When the plants are "in the rough," that is, have made leaves beyond the seed-leaves, they should be hoed and thinned. The usual method is to cut across the rows with a sharp hoe, leaving a bunch of plants at every ten or twelve inches, and then go over again and remove all but the strongest plant. After the thinning, the spaces between the rows must be kept clear of weeds by the use of the cultivator, aided by the hand-hoe near the plants. The varieties of Ruta Baga are numerous, and other things being equal, those the form of which is most nearly globular are to be preferred. Those who grow turnips largely, raise their own seed, and thus secure a strain suited to their land. The Aberdeen and Yellowstone may be sown any time up to August 1st; they are excellent for feeding and for the table, but do not keep so well as the Ruta Bagas. In preparing the land for turnips, a dressing of three hundred pounds to the acre of a good superphosphate, will be a profitable application. The soil must be rich and mellow for turnips.

A Reversible Watering Trough.

Mr. I. E. Charles, Maple Grove, Ind., sends us a sketch and description of a watering trough. Saw in two a strong barrel or cask, as a coal oil barrel, about the middle, and bore a hole on opposite sides near the top with a two-inch auger. Set two posts of scantling or round timber in the earth,

TUB WATERING TROUGH.

boring holes in the top to correspond with those in the half barrel. Strong wooden pins, oak or hickory, support the trough, as shown in the engraving. The trough can be inverted to throw out any water after a horse or cow has drank. It may be set near a pump with a trench below to carry off the waste water. Such a barrel trough is especially convenient in winter when otherwise the trough would get filled with snow and ice.

Raising Chickens.

Do not be in a hurry to invest in incubators, if you are a farmer, and have anything else to do besides looking after the poultry yard. The wooden incubators are well enough for men who have plenty of money, and make the raising of eggs and chickens a specialty. A good many things about incubators are not yet proved, and a farmer who has his bread to earn, can afford to wait a little

longer, and use the original method for hatching and raising chickens. The hen is good for a dozen eggs, and, if she be left to her own selection of nest, is pretty sure to hatch them, if they are fertilized. You may protect her against vermin, but she covets privacy, and desires to be left alone. When her brood is off, she needs a little help, a coop for shelter, and regular feeding with a mixed diet of animal and vegetable food, and water or milk to drink—the latter if you can get it. Nothing is better than milk for the fowls. The young chicks will help, rather than hinder in the garden, until they are a month or six weeks old. They will destroy a multitude of insects, and thrive on them. The early hatched chickens are best for layers, but late summer is quite as good for broilers. They never come amiss at any time on the farm.

Among the Farmers.—NEW SERIES, No. 3.

BY ONE OF THEM.

I was in Central Vermont last spring, and noticed many fields where Indian corn would soon be waving its broad leaves, upon which the manure had been hauled out last autumn, and left in small heaps. At first I thought that the intention of the farmers must have been to spread it and plow it under at once, and so it may have been, when winter came on, and stopped all such work. But there were so many fields in this condition, that I concluded it was a common practice to leave the manure out all winter, and plow it in in the spring. It would not do at all in New Jersey, and is wasteful anywhere. When frozen solid there is not much loss, and lying unprotected a little while in autumn, and six weeks in the spring, the loss is not very serious, but it certainly is better to have it spread uniformly over the ground, where it will not wash, or to place it in large heaps where it will go on ripening for most of the winter, even if it should be under the snow, and the outside temperature be twenty below zero. No doubt the reason for this practice of getting out manure in the fall, is because the winters are so long, and the northern farmers cannot haul out on the snow as we can. They have two to four feet of snow, and this, of course, confines travel to the beaten paths. With a foot of snow, settled to four inches by a rain or a few warm days, and then frozen solid, we can haul manure anywhere, and do many other things.

Manure Spreaders.

With one Vermont farmer the necessity for getting ready for early plowing, no doubt suggested the admirable manure spreader now in universal use among the gentlemen farmers (of whom I wrote in my last article), and by some other enterprising and reading men. It is amazing how slow such a great labor-saving, and time-saving, implement is in coming into general use by those who would be most benefited by it. I presume there are hundreds of readers of the *American Agriculturist*, who have never even heard of it. This manure spreader consists of a cart body, which may be set at an inclination to the rear, where there is a very simple arrangement in the place of the back-board, operated by the wheels automatically. This implement spreads the manure over a space as wide as the cart track, or a little wider, and much more uniformly than it could be done by hand, and as rapidly as the team can walk. Two or three neighbors, each owning a manure spreader, sometimes combine, and all meet at one farm, and so manure the corn land in one day perhaps. Thus the man whose land is ready first does not have to wait long before his plows are running, while, quite likely, the others will have the same advantage, as soon as their land is dry enough to plow.

House and Barn Connected.

I had entirely forgotten a noticeable feature of Vermont farming—for it is years since I was in the Green Mountain State. It is this: Almost all the barns are built contiguous to the houses; in many cases the barn is really an "L" to the house. It was easy to see the reason for this, or at least imagine it. I thought of a snow storm among these hills, and of the comfort it must be, when the snow is

piled up as high as the tops of the windows, and there is no getting about, for the farmer to be able to care for his cattle, and do his milking and "chores" without digging through an eighth of a mile or less of drifted snow, or tunneling through a drift before he could even get sight of his barn. In this part of the country I am sure we put our houses and barns too far apart for convenience in winter, and yet they are safer in case of fire. Besides, our house wells are quite near enough to the barnyards. Up there among the hills, the water comes down in wooden pipes from some mountain spring, so the nearness to the barnyard is not of so much consequence.

Pure Drinking Water.

This matter of pure water to drink, is vital, *vital*, *vital* to the well-being of farmers. It may be all very well for the good of the race, for the puny, delicate, "peaked" children to die, but these are the ones that the mothers, at least, love best, and there is a vast deal of rending of hearts over the sickness and death of the delicate ones, young or old, which might at least be postponed for many years, if they and we had pure water to drink. Wells near barnyards, or within two or three hundred feet of them, sometimes contain the germs of disease and death. The old fashioned privy vault, fifty times more dangerous, is usually nearer the house and the well, and contrived, as if by the "arch-enemy," as an unfailing source of malarial poison, of diphtheria, typhus and typhoid fevers, and the evils that follow in their train. There ought to be State laws forbidding the existence of the privy vaults, or even of cess-pools, except, perhaps, cemented cisterns, through which a regular flow of water is maintained.

No system was ever devised equal to the Mosaic, (Deut. xxiii ; 12, 13 and 14,) but that is particularly adapted to a nomadic people, although I have met with it in Louisiana and Kentucky, and know it is the rule in Texas, where the abomination alluded to has never existed, except to a very limited degree.

Milk Cows.

There has been a good deal of discussion lately in some newspapers, as to whether it is best to raise or to buy milk cows. This is a question like many others, "with two sides to it." When "once upon a time," some one said that everything had two sides, his opponent thought he gave him a "poser" when he asked "on which side of a piteher is the handle?" It did not take long to find out that it was on the outside, and so in this matter of raising cows, there is an inside and an outside. In Cattaraugus, and other New York counties, the farmers long ago were wise enough to procure full-blooded Shorthorn bulls, and these have given rise to a style of cows which is very prevalent there, and is just what our milk producers want. They can be raised there for about twenty dollars a head, cost the buyer thirty dollars, and so the raiser has a fair profit. No more is asked for a four or five-year-old cow, which has given two calves, and probably four thousand quarts of milk. The raiser can well afford to sell rather than winter some of his cows, and where milk is worth an average of three cents a quart the year round, farmers can not afford to raise calves dropped at any time before the middle of May. Calves may indeed be raised without milk, but they are not the ones that make the best cows, and if raised upon milk, they will cost the farmer, to say the least, a great deal more than anybody will give him for them. The danger of importing disease is very slight. I would never advise a man to buy cows out of a travelling herd, but there are in every dairy section, enterprising men, usually first class farmers, who go into the cow-raising counties, and buy four and five-year-old "springers" (cows soon due to calve). They buy of men whom they know, pick up two or three car-loads, and arrange to have them shipped, one car-load at a time, as ordered. Often these dealers know the cows, and have watched them as they grew, as two, three, and four-year-olds. They are healthy, large milkers, and seldom go wrong, and are sold at prices decidedly lower than the milk-producer could have raised them for himself.

If a milk-farmer has a grand, twenty or thirty-quart cow, and wants to raise her heifer calf, and get one to be really proud of, let him send her to a first rate Jersey or Guernsey bull, so that she will come in in May. Then arrange to raise the calf on skim milk, and to do well by it, and he will probably get a cow giving sixteen to twenty quarts of very rich milk. The drifting herds I speak of, are usually picked up by an inferior class of dealers, in places not far removed from the milk section. They attend auction sales, and get any kind of "springers," and cows with young calves, they can buy. They move slowly through the milk region, towards the cities, where they are sure of some sort of a market, and they constantly trade and barter along the route. Of course there is great danger of getting disease in one's herd in buying such cows, and it is a blessing that these drifting herds generally head east, where they soon become beef, and that now-a-days there are comparatively few of them.

Keeping Hams through the Summer.

It is somewhat difficult to guard hams from flies through the summer, however well cured and smoked. The smoke-house, if well made, preserves them, and this is the more common place of deposit with those who smoke their own hams. But multitudes have on hand a season's supply of hams and shoulders. They keep much better in a dry atmosphere. If sugar-cured hams are purchased, the cloth that covers them is a sufficient protection against insects. If the hams are home-cured, they can be covered with cloth at small expense, or even with a bag of thick paper tied tight at the top, around the string by which they are suspended. If hung in a dry, cool place, they will not mould, and will always be on hand for the staple of a hearty meal, in any emergency of the family. Farmers generally make their own meat, and cure it, and, with a good recipe for curing, secure better hams than they can purchase, and at less cost. It pays to keep the larder well stocked with the best.

Preparing Sumach for Market.

Certain inquiries seem to be perennial; a crop of them coming each year with the return of summer, probably from new subscribers who have not seen former volumes. Sumach is one of these perennial subjects. The first inquiry this season came from W. P. Gould, Clay Co., W. Va., and in answering him, we reply to several others. The two species most commonly gathered, are the Smooth, or Common Sumach (*Rhus glabra*), and the Staghorn Sumach (*R. typhina*). The Mountain Sumach (*R. copallina*) is equally valuable. The first two are found nearly all over the older States, while the other is somewhat less common. The tops of the bushes and ends of the branches are broken off and laid upon roofs, on hard bare places upon the ground, under sheds, etc., where they remain until dry. It is then threshed with sticks, the twigs and stalks picked out, and the leaves packed in sacks, bed-clothing, or whatever will hold them on their journey to the mill. Herein is the difficulty in sumach collecting. The article is not marketable until the leaves have been ground fine and bolted. The machinery or plant required to do this, costs more than a collector of the leaves can afford, hence the business, to be profitable, requires a mill, and within easy reach of numerous collectors, as the crude leaves are too bulky to warrant packing and shipping to a distant mill. The business of preparing sumach for market, is mainly confined to Richmond, and some other cities of Virginia. The collectors take their small lots to the mills, where they are bought. After the sumach is properly manufactured, it is sent for sale to New York and other cities, where it comes in competition with the imported, or Sicilian Sumach, which is the leaves of *Rhus coriaria*, a species cultivated in southern Europe. However abundantly sumach may grow in a locality, unless the owner of some grist mill will introduce machinery to grind and bolt the leaves, or some capitalist will establish a mill for the purpose, the gathering of the sumach crop can not be made profitable.

Propagation of Trees by Layering.

A. S. FULLER.

Layers are really nothing more than a form of cutting, the only difference being that they are allowed to adhere or remain attached to the parent stock—drawing sustenance therefrom until roots are emitted, after which they are detached and become individual plants. In making layers of trees or shrubs, we bend down a branch, and cover that portion with earth upon which we wish to produce roots. Figure 1 shows a layered branch buried

Fig. 1.—A LAYERED BRANCH.

in the soil. An incision is usually made on the under side of the branch before it is laid down, and the knife inserted just below a bud if there is one convenient, passing into the wood, and then an inch or more lengthwise of the branch, forming what is termed a tongue, as at *a*. A hooked peg, *c*, may be employed to hold the layer in place, or a stone laid on it, as it is quite important that the branch be held firmly in place. If the branch is large, the end may be tied up to a stake, as shown at *b*. It is not often that forest trees, except some ornamental varieties, are propagated in this way, but it is well enough to know how to do it, when necessary to increase the stock of some choice or rare specimen. Layers may be made at almost any season, but they will root sooner if made when the trees are growing rapidly, than at any other time.

Some kinds of trees will produce roots when layered without cutting the branch, and exposing the alburnum—in fact, all will, in time, but the surest way is to cut the branch as described. With some kinds, roots will be emitted so slowly that the layer must remain at least two seasons before it will be safe to sever it from the parent stock. Evergreens may be layered in the same way as deciduous trees, but the operation should always be performed during the period of active growth, else the wound made on the layer is likely to be covered with resin, which may prevent the emission of roots.

Fig. 2.—POT LAYERING.

Sometimes a part of a tree or a small branch will vary from the original; when this occurs on a large tree and where the branch cannot be made to reach the ground, we are compelled to elevate the soil, or some similar material to the part we wish to propagate, unless it is some species which can be readily propagated from cuttings, buds, or grafting. If we desire to obtain a layer, we have only to place a pot or box of soil near the branch, so that it can be covered with earth, the same as if near the ground. After the branch is layered, the soil surrounding it must be kept moist until roots are produced. Figure 2 shows a branch layered in a pot from which a piece has been taken from one side to admit the branch; the crevice is closed with a piece of board or shingle placed on the inside of the pot, after which the pot is filled with soil. If the pot is surrounded with cloth or moss, it will in a measure prevent the earth from drying, and therefore less frequent waterings will be required.

Various Garden Structures.

The beauty as well as the enjoyment of a garden may be greatly enhanced by the introduction of structures, the utility of which is apparent. If there

Fig. 1.—A STILE FOR HEDGES.

is a high eminence, it may be appropriately surmounted by an observatory, to allow of a still more extended view. If there is a lake or a stream, bridges will be suggested, and a boat-house may often be desirable. If there are ornamental fences, gates with ornaments are required, or if the grounds are divided by hedges, stiles will be needed. While garden structures are, as a rule, made in winter, summer, the time when the garden is most frequented, is the proper season for selecting the localities for them, and the best for judging what their effect will be. Summer is also a good time in which to select the material, though it may not be made up until winter. The several designs here given are those suggested by Mr. Elias A. Long, a landscape gardener of Buffalo, N. Y.

STILES.—Ornamental hedges are much more generally used than formerly, and in some localities they largely serve the purpose of boundary fences. One of the objections to a hedge is the difficulty in crossing it. A gate in a hedge seems out of place, and the stiles are usually cumbersome structures. There is no reason why a stile should not be as portable as a step-ladder, to be used wherever it is needed. Figure 1 shows how a stile of this kind may be built. The two parts, where they cross, are held together by bolts, or a single long bolt may be used; the curved form of the sides allows it to be employed without resting on and injuring the hedge.

BRIDGES.—Whoever has a stream, however small, running through his grounds can produce a variety of ornamental features. It may be improved as a stream, it may often be made to form a small lake, or its current may be dammed to produce pleasing cascades. A stream will often require the introduction of a bridge, or, in some cases, a bridge may cross a dry ravine. A bridge should be abundantly strong in its roadway, and the railings, while they may be ornamental, should always convey the idea of sufficient strength. Rustic bridges are very pleasing, and the design given in figure 2, is easily executed by the use of the branches of Red Cedar. In some places a bridge may be constructed of rocks, and be in better keeping with the surround-

Fig. 2.—A RUSTIC BRIDGE.

ings than a more elaborate structure would be. Figure 3 will afford a suggestion for building bridges of this kind. Rustic and rock bridges may be made still more picturesque by trailing the Virginia Creeper, and other hardy climbers upon them.

SUMMER HOUSES.—Some fifty years ago it was thought necessary for every garden, large or small, to have a summer-house. These were cumbersome structures of timber and boards, with shingled roofs, and usually painted white, with green blinds. They were rarely used, but given over to cobwebs

and dust, and generally became convenient tool-houses for the garden. A rustic summer-house may often be introduced as a picturesque object in the grounds, and may be a pleasing resort for reading, sewing, etc., in hot weather. A summer-house may often fitly crown a high portion of the grounds, wherever an extended view may be had, or an abrupt promontory on a lake. Figure 4, gives a pleasing design for a rustic summer-house of a hexagonal form. It is built of Red Cedar, with three sides closed and three open. The interior is finished in small, straight branches of cedar, nailed on obliquely. The exterior of the closed sides, and the two half open sides, are finished in pieces of cedar poles, about three inches in diameter, and split in halves; these are nailed on as shown in the engraving. The roof is thatched with straw, laid on from nine to twelve inches thick; this serves to keep the interior cool, and accords with the rustic style.

The Importance of a Supply of Wood.

No one who is at all familiar with forests and their products, needs to be reminded of the importance of having at hand an abundance of wood of various kinds, or how much it contributes to the general welfare and happiness of a nation. But there are those who have not paid much attention to this subject, who claim, and no doubt honestly believe, that the great progress made of late years in the use of iron in the place of wood in building houses, bridges, piers, ships, and other structures, are but indications of what is to follow, and that in a few years there will be no great demand for wood.

The building of railroads, which reach almost every part of the country, has aided in the distribution of coal, and made this in a great measure a more convenient, and in many instances a cheaper fuel than wood, but in building these roads a vast quantity of wood has been used, and of the best kinds, not only for ties, of which nearly or quite three thousand are put down per mile, but on many of the roads wood is still used for fuel. There is now nearly or quite one hundred thousand miles of railroads in the United States, and we have only to multiply this by three thousand, to ascertain that three hundred millions of ties have been used in their construction, leaving out of account the thousands of wooden bridges and other structures, in the building of which more or less wood has been consumed. The railroads may have assisted very materially in checking the consumption of wood for fuel, but they have probably more than balanced the account in the amount used in their construction, besides the three hundred million of ties must be duplicated every ten years, for the average life of a railroad tie will scarcely exceed a decade, and with nearly all kinds, except the best oak, it is a year or two less.

The demand for railroad ties is not likely to decrease, but increase, although as timber becomes

and while it has done much towards making it possible to produce sufficient iron to meet the great and constantly increasing demand, it has not superseded charcoal, and there is probably more charcoal used to-day than at the time coke was first employed in a smelting furnace. Charcoal is still used in furnaces and forges, and there are several establishments in this country that use annually over a million bushels each, and a score of others that consume from twenty to twenty-five hundred thousand bushels.

Notwithstanding the number of substitutes that are employed, the demand for and consumption of wood appears to increase, and to-day there is probably more wood used for making boxes of various kinds than there was in the construction of buildings of all kinds in the country three-quarters of a century ago. Furthermore, no kind or quality of timber appears to escape the insatiate demand of the artisan of the period, and he not only finds ready uses for the large and small, the hardest, toughest, and most durable, but also for the soft and spongy, the latter being preferred for grinding up into wood-pulp for making paper.

Not a year passes during which scores of new devices and inventions of new articles of manufac-

Fig. 4.—A RUSTIC SUMMER-HOUSE.

ture, are not brought forward, that are made in part or wholly of wood, and while singly they may not call for a great quantity, they do in the aggregate use up an enormous amount of the material.

The invention of a pleasing toy for children has frequently caused the demolishing of hundreds of acres of forests, to supply the manufacture with wood used in its construction. It is idle to talk of

Fig. 3.—A BRIDGE OF ROCKS.

scarce and prices advance, preserving processes will doubtless be employed to prevent rapid decay. Stone, brick, and iron will also come into more general use for buildings, but the increase in population will also tend to increase the demand for wood for other purposes besides that of buildings.

It is only a little more than a century since coke was first employed for smelting iron ores. The introduction of this fuel to take the place of charcoal, it was thought would save the forests of the world from destruction by the charcoal burners,

our natural forests furnishing a supply of wood for the future use of our people, even with the most careful management and economy in preventing waste, there must soon come a time of great scarcity of all kinds of wood. With an increase in population, there must necessarily follow a corresponding increased demand, because experience has shown, that whenever any other material has been substituted for wood, it merely releases a certain amount, and allows it to seek other channels or markets. No matter in what direction we turn, the fact meets

us, that the best and most valuable forests of the United States are rapidly disappearing, and the sooner we commence as a nation to economize in the use of wood of all kinds, and preserve the forests now existing, as well as commence the planting of new ones, the better it will be for the present as well as future generation.

It is not necessary to select the best and most fertile land upon which to raise trees, for any that is rich enough to give the plants a good start in life will answer, because the annual dressing of leaves that the soil receives will be sufficient to keep the trees growing. There are doubtless many situations, where a single tree would not thrive, as on a prairie, a bleak hillside, or other exposed positions, where by planting a number together, they would mutually protect each other, and usually take care of themselves. We have millions of acres of barren, naked, sandy, rocky, and otherwise unproductive lands, that might readily be covered with valuable forests. Large plantations of forest trees have been established in Europe, and there is no good reason why the same should not be done in America. Let us do it now. A. S. F.

The Water Uintjies.

Those who have upon their grounds a small body of water, no matter how small, provided it does not dry up in summer, can enjoy a number of beautiful and interesting plants, which can only be grown as aquatics. A collection of the Water Lilies, which, besides our own, with its rich fragrance and dazzling whiteness, together with its fine pink variety, would include exotic red, blue and other species. Besides the water lilies, there are a number of less conspicuous plants, none of which are more desirable than the Water Uintjies. We have not been able to find out what "Uintjies" means, but it is said to be a term applied at the Cape of Good Hope to the plant known to the botanists as *Aponogeton distachyon*, an aquatic plant related to our native Arrowhead, so common in swamps. *Aponogeton* is said to be a mongrel name, between Celtic and Greek, and to mean "near water," which is not very descriptive of this plant, which is a thorough aquatic. From a tuber about the size of a hen's egg, there arise numerous leaves, upon long, slender leaf-stalks. The leaves float, are from a foot to eighteen inches long, of the shape shown in the engraving, and of a clear green color. The flower stalks arise among the leaves, are divided at the top to form two branches, upon the surface of which are placed the flowers. These have neither calyx nor corolla; they consist of obtuse, ivory-white

THE WATER UINTJIES (*Aponogeton distachyon*).

bracts, in the axils of each of which are twelve stamens, with dark-purple anthers, and four to six pistils. The plant is odd in its general appearance, but is noted for its abundant and most exquisite fragrance. It flowers continuously all summer. Though it comes from the Cape, it is hardy in New

England, and would probably be so in all but the very severe portions of our country. It is said that the flower-stalks and tubers are eaten in Africa.

Isolated Trees with Decorative Surroundings.

Much of the French decorative planting is too elaborate to be successfully copied in our climate. They have, however, a method of surrounding isolated trees upon a lawn, which may sometimes be adopted by us with good effect. Mr. Edward André, one of the most judicious French garden designers, in communicating the illustration to the "Revue Horticole," which we here reproduce, says that this is a kind of ornamentation that may easily be overdone, and advises great moderation in its employment. It is best suited to young specimen conifers, furnished with branches quite to the ground, such as a well-grown spruce, a Lawson's cypress, etc. Gay flowers would be out of place, the object being to make use of colors that will make a striking contrast with the lawn. In the example illustrated, a circular bed of some dark colored *Coleus* was planted next to the tree, and extending quite up to it. This was surrounded by a many-pointed star with rounded angles planted with "Dusty Miller" (*Cineraria maritima*), kept low by severe cutting. At the points, or where the adjoining arcs unite, small circles are formed in the middle of each of which are plants of *Iresine acuminata*. We give this design as a suggestion, and one capable of being varied in many ways. Ivy, pegged down, and the Golden-netted Japanese Honeysuckle, the charming *Retinispora plumosa aurea*, which may be kept at a height of a few inches might be planted. Ivy with Dusty Miller makes a fine contrast. Indeed one who wishes to attempt this kind of ornamentation will find an abundance of materials suited to the purpose.

A TREE SURROUNDED BY A BORDER.

Grapes Here and There—The Ives.

Some twenty years ago the Concord was advertised far and wide as "The Grape for the Million." It was indeed successful over a wide extent of country, and did much to popularize grape culture, as it would yield grapes under neglect. But after a while localities were discovered in which even the Concord would rot, and was worthless. It was generally successful—with exceptions. Then came the Ives grape, an Ohio seedling, probably of the Hartford Prolific, for which was claimed all the good qualities of the Concord, and a superiority to that variety as a wine grape. Some eighteen years ago we visited the first vineyard of the Ives, ever planted, and more healthy, fruitful, vines were never seen. As to quality, not much can be said; there are some poorer grapes, and many better, but it seemed that one who had a vine of the Ives, would have an abundance of grapes, and his success with this indifferent kind would lead to a trial of better varieties. Wishing to know more about the Ives, we planted six vines of this variety

in our experimental vineyard. When these came into bearing, they bore abundantly, but failed to ripen. The berries, when full-grown, cracked open, rotted, and did everything that a grape ought not to do. After this had been repeated year after year, the number of vines of the Ives was reduced to two. Several years ago, Mr. Geo. A. Meissner, one of our most intelligent viticulturists, called on us; in a general talk upon grapes, we gave him our experience with the Ives. This so astonished him,

that we brought him specimens of the fruit, that at that time should be just ripening. After keeping two vines of the Ives for several years, the number was reduced to one, which is continued as an instructive specimen. Some weeks ago, in writing Mr. Meissner, among other grape gossip, we mentioned, in reference to a former conversation, that our remaining vine of the Ives, in a vineyard of over fifty varieties, had never given us a single perfect berry. In reply, Mr. M. wrote the following, which, though in a private letter, is so full of good sense, that we venture to publish it. He says: "What you say with reference to Ives and Elvira with you, proves again that we must not expect any variety to do well in all different sections. The Ives is, here, Jefferson Co., Mo., and especially in the country south and southeast of here, one of the most reliable and surest grapes, though its quality is always inferior, compared with the finer and better varieties. The Elvira, on the other hand, is rapidly growing in favor, especially in the lake regions of Ohio, on the islands in Lake Erie, etc., where it is now being planted very extensively." Here follow these words of wisdom from a grape-grower of the widest experience, which we commend to those who are searching for "the grape for the million." Mr. Meissner continues: "Thus every section will have varieties which are specially adapted to its locality, soil and climate. But in this very question of adaptability of the varieties, there is yet a great deal to be learned. Experience is the best teacher in this matter." Let us hear no more about "the grape for the million," but let each cultivator endeavor to ascertain which varieties of grapes are best for his locality and soil. With the grape, as with other fruits, catalogues are not a sure guide. Neighborhood experience is much better than that of wider districts.

Growing House Plants in Moss.

In some of the Swiss villages, nearly all the inhabitants are engaged in watch-making. They work in large rooms, which, being abundantly lighted, and well warmed, allow the workmen to cultivate plants, that, on account of the uncertainty and rigor of the climate, can not be grown in the open air. The President of one of the local horticultural societies in Switzerland gives, in the "Revue Horticole," an account of the great success with which plants are cultivated in moss in these watch factories. One great advantage in the use of moss, is the readiness with which plants may be grouped in large vases and boxes. In France a "fertilized moss" is sold, but ordinary moss, with occasional application of liquid fertilizers, will answer as well. Ordinary sphagnum, or peat moss, such as is used by florists in packing, may be employed, but the writer prefers the moss which grows in sheets upon rocks, and around the trunks of trees at their base. Wire baskets lined with this moss are used, as are jardinières of metal, glazed pottery, etc., taking care to provide sufficient drainage. The liquid fertilizer used on these house plants, should be without unpleasant odor; weak guano water, solutions of nitrate of soda, or sulphate of ammonia, may be employed, and very fine flour of bone may be mixed with the moss.

Notes From the Pines.

Having long cultivated our native plants, many readers and friends, when they come across unusual forms of these have kindly sent them to me, and my collection shows that double flowers occur in nature more frequently than is generally supposed. A dozen or more years ago, a young man sent me from a town in Massachusetts

A DOUBLE EARLY SAXIFRAGE.

This (*Saxifraga Virginicensis*) is a very common wild flower, and one of the earliest, but as the center of the little white flowers is greenish, they are not very handsome. The double flowers were little balls of pure white petals and really beautiful. The plant did not live, and I often regretted its loss. Last year a lady brought us, perhaps a dozen plants, of this same double Saxifrage, which she had collected within a few miles of this place, and afterwards brought more, showing that double flowers are not always due to cultivation. Two other early wild species, the Wood Anemone (*A. nemorosa*), and the Rue Anemone (*Thalictrum anemonoides*), occasionally occur double, and have been for sometime in commerce, I had long

Fig. 1.—A DOUBLE-FLOWERED MARSH MARIGOLD.

known of, and once before imported, but never until this spring succeeded in flowering the

DOUBLE MARSH MARIGOLD.

The single form of this, (*Caltha palustris*), which is often incorrectly called Cowslip, makes the

brook sides and wet places bright with its golden-yellow flowers, the petals of which shine as if varnished. The double flowers, and they are very double, are little hemispheres (fig. 1) of the same brilliant golden-yellow. All double flowers are, as a rule, more lasting than the single ones of the same kind, as notably seen in the single and double geraniums. The double *Caltha* lasts for many days,

Fig. 2.—A NEW VARIETY OF MOSS-PINK.

while the single flowers soon fall away. It remains to be seen if this plant can adapt itself to garden soil. Variations in color in wild plants are quite common. Many blue or red, or purplish species having white forms. The Bird's-foot Violet (*V. pedata*), the largest flowered of our wild violets, often changes its pale violet-blue for pure white, and still more rarely, two of the petals are of an intense purple color, and velvety like a pansy.

THE MOSS PINK, OR DWARF PHLOX,

(*Phlox subulata*), usually of bright rosy-purple, is sometimes a snowy white. This occurs in the wild plant and shows a natural tendency to vary. An English amateur florist, the Rev. John Nelson, took this Phlox in hand, and in raising a large number of seedlings, was rewarded by several well-marked forms. The flowers in these varieties, one of which is given in fig. 2, are varied with pale-pink and dark-purple markings in a striking manner. About a dozen of these have been named and put into commerce. The success of Mr. Nelson, with one of our common wild flowers, should encourage our own amateurs to experiment in this direction, while the work would be interesting, a marked success in the production of new desirable forms would have its pecuniary reward. PINES.

Harvesting and Storing Onions and Onion-Sets.

Those who supply the city markets, are wise if they do not have many onions to store for the winter. If bunched and sold as green onions, they bring much more than when quite ripe. A dozen half-grown, or even smaller onions, and half a dozen of full size, usually make a bunch. When from two-thirds to three-fourths of the onion tops turn yellow and fall over, the crop may be pulled, laying the bulbs from two or three rows together, with their tops all in one direction. The onions are left here to complete ripening. If a storm comes on, they may be laid up in casks, and spread again as soon as it is over. When the top, at the neck, or where it joins the bulb, is twisted and no moisture exudes, they are dry enough to store. The tops are cut off at about an inch from the bulb, and they are spread in a cool airy loft, not more than two feet thick. On account of the difficulty of keeping them, many growers ship their onions directly from the field. On account of the marked fluctuations in the price, others prefer to store them, and take advantage of a sudden rise in the market. The chief difficulty in keeping onions is, their tendency to heat. It does not hurt them to be frozen, if they can be thawed very gradually. If onions in barrels or bulk are frozen, it is well to cover them with hay to the depth of several feet, and keep them in a frozen state as long as possible.

ONION-SETS show when they are ripe in the same

manner as large onions, by the turning yellow and falling down of the tops. It is best to shear off the tops as the sets stand in the rows. They are taken up by running a trowel under them, and throwing them upon a coarse sieve, which will allow the soil to be separated. Store the sets in a loft, spread not thicker than three or four inches. At the approach of cold weather, throw them into heaps, and cover with hay or straw, or with mats. If they freeze, keep them frozen as long as possible. Those who raise onion-sets for their own planting, need have no difficulty in storing them, as it is much better to plant them in autumn; they are perfectly hardy, and if planted then, will give an earlier and larger crop than if set out in spring. The land for planting sets should be as well enriched, and as thoroughly worked, as for sowing the seed ("black seed," in spring. Mark out drills nine inches apart, leaving six drills in a bed, and omitting the seventh for a path. In planting the sets, take care to get them right end up, placing them about three inches apart, and pressing them well down into the soft mellow soil; cover the rows well with soil, using the feet, or by the use of a rake, and finish the planting by rolling the ground.

ONIONS FOR SEED.—Those who raise onion seed, should carefully select the bulbs at harvest time, choosing not only the largest, but those of a shape nearest like that desired for the future crop. These large selected onions are even more difficult to keep through the winter than the general crop, and on this account, as well as others, it is better to set them out in the fall, October being usually the preferable month. The land for seed onions should be fairly rich, and marked out in rows about two and a half feet apart. The onions are to be set about six inches apart; the only precaution to be taken, is to be sure that the bulbs have a covering of at least three inches of fine mellow soil.

Strawberries for Next Summer.

Whether we make a bed the coming fall, or next spring, by setting out plants from runners that have taken root in an old bed, a fair crop of fruit can not be expected until 1886. A few scattered berries may be borne, but nothing like a crop, until such plants have been in their new location for a year. The only way in which it is possible to prepare a bed that will afford a crop next spring, is to set out pot-layered plants. At present, nearly all of the nurserymen supply pot-layered plants; it is true that they cost more than plants dug up from the beds where they have taken root, but only enough more to pay for the extra trouble. If one has an established bed, he can easily strike the runners in pots himself. The earliest runners will give the strongest plants, but it is not too late to layer them early this month. Small pots, two or three inches across the top, are to be filled with light rich soil. Strong runners, just about to take root are selected, and a pot of soil is set or plunged in the soil of the bed, directly under each runner, planting the pot well down, so that its edge will be on a level with the surface of the bed. Place the runner, or rather the young plant at the end of it, in the centre of the pot, and hold it in place to prevent it being blown about, by the use of small hooked pegs, pieces of wire bent like a hair-pin, or even by laying a small elod or stone upon it. When well rooted, which will be in about three weeks, the slender stem that connects the new plant with the old, may be cut, and the potted plants will be ready to set out in the new bed. The sooner such plants can be set out the better, August being the best time if the plants are ready. The bed being well prepared, and manured, set the plants in rows two feet apart, with eighteen inches between them in the row. Give the pots a thorough watering, and the ball of earth may be turned out without the least disturbance of the roots. In a dry time the plants should be watered, and all runners that appear upon them are to be pinched off, in order to concentrate the growth in the crown. At the approach of winter, cover the bed with straw; it should lie thinly over the plants, and thicker between them.

Awnings for Country Dwellings.

Blinds are convenient to protect glass, shut out the sun and admit air, but they are far less desirable for summer than awnings, which afford ample shade without excluding abundant light and ventilation; and standing further from the window, they more effectively ward off the sun's heat. Those made at the shops, with iron frames, cords, pulleys, etc., are expensive; but any one can construct simple good looking ones, with small outlay and little work, which will be sufficient to protect windows from hail stones. We give our own method, which works well.—Two pine pieces, one by two inches, are cut as long as the window is wide. Two similar pieces of desired length are nailed to these at the corners—or may be halved on to them—to form the frame, (fig. 1), which is strengthened by short braces at the upper corners. A strap hinge at the back of each lower corner screwed to the window frame, allows the top to turn out and down to a horizontal position. Suitable cloth is tacked to the top window casing or frame, carried slanting to and over the outside bar when let down, tacked to it, and extended six or eight inches further, to form a valance, with its edge scalloped as seen in figure 2. A triangular piece is fitted to each side, sewed at the top, tacked to the side of the frame, and the lower side scalloped continues the front border round the three sides. A cord, shown by the dotted line, extends from the center of the outer bar to an eye at the middle of the top of the window, thence to a side eye, and hangs down. Pulling on this raises the frame,

Fig. 1.

Fig. 2.

gathering the cloth against the top of the window, at evening and on cloudy days. After a rain, the awning should be shaken out to dry, to prevent rotting or decay. With this care, such an awning will last for years. Almost any cheap cloth will answer temporarily, and may be reversed; but good, strong fabric will cost but little more, the work of construction will be the same; it will show better, and be far more durable. The whole expense outside of the cloth will be a trifle, for the pine sticks, two hinges, a few screws and nails, cord and staples.

Shawl Bags.

A bag is a capital thing to save a shawl from the dust of a journey and, if of good size, can be used for holding toilet articles, etc. The best material

A BAG FOR SHAWLS.

for making shawl bags is brown water-proof. Cut two round end pieces eight inches in diameter, and a piece twenty inches wide by twenty-five inches long. Stitch these together, leaving the straight

seam open nearly all the way across, and bind its edges and the edges of the end-pieces with worsted braid, sewed on with the machine. Close the opening with three buttons and button-holes. Stitch a piece of braid on a band of the water-proof two inches wide, and fasten on firmly for handles. The outside pocket can be made of any size or left off, but it is very convenient for papers. The bag shown in the engraving has an extra row of braid stitched on, but that is left entirely to the taste of the one who is to use it. A person while travelling will never wish to be without one of the shawl bags, after finding out how useful they are.

Wash-Stand Screen.

The screen shown in the engraving is made over a hoop, the diameter of which should correspond

A ROUND WASH-STAND SCREEN.

to the width of the wash stand. Cover the hoop as smoothly and tightly as possible with some bright-colored cambrie or Silesia, and make an outside covering of plain or cotton Swiss, half the width of the hoop, and long enough to full on slightly. Gather the opposite edge, and after fastening it firmly on the outside of the hoop, draw it down to the center and finish it with a large bow of ribbon of the same color as the lining. The edge should be finished with a Swiss ruffle, about three inches wide, worked in "herring-bone" stitch, with worsted. Make a loop on the back by which to hang it up, and suspend it so that only three quarters of the screen can be seen.

Wedding Presents.—Beginning House-Keeping.

Everybody likes to receive wedding cards. But with this pleasure often comes the perplexing query, "What shall I give?" The custom of exhibiting wedding presents, is a questionable, if not a vulgar one; and the story of a bride who received so few, that she felt obliged to hire from a jeweler sufficient silver-ware to make a good display, is an intimation of the desire people have, to make their presents show to the best advantage. It would not be strange if the smaller presents were sometimes hid behind the larger, even though the latter, sent because "they must send something that would show well," were unaccompanied by the sincere regard which went with the former. Of course, much uncomfortable, if not bitter feeling results, and unless one can feel independent enough not to care, it is better to give in a less public way. To those who are about to commence housekeeping, a most acceptable gift, and one of which housekeepers in general know the value too well to ridicule, would be a willow basket of suitable size and shape, containing six linen hemmed towels for glass and silver; six soft linen crash dish towels; three hemmed cloths for washing dishes; three soft linen cloths for washing glass and silver, and three cloths, knit of fishers' twine, for washing pots and kettles; three flannel cloths, hemmed, for washing paint, etc.; three roller towels of linen crash, two yards long. These may be added to by

the donor in many inexpensive ways. Another helpful gift would be a home-made book. The covers are of gray, brown or black Bristol board, bound with satin, with a spray of flowers painted on them in water colors, or they may be covered with satin, and the flowers embroidered on them. Inside are seven cards of the size of the covers, and of white board, with each day of the week—one on each card—written in illuminated letters at the top. These are intended for the young mistress to write down the special work of each day, and hang the card for the day in the kitchen for reference. This is a great help to system and order in the home. We confess great sympathy for the young mistress who, hitherto unaccustomed to care or responsibility, finds herself at the head of a home which she is to keep up in all its appointments. The table is to be supplied with palatable and nutritious food three times every day, or one thousand and ninety-five meals in the year; the house to be kept neat and wholesome; company to be entertained, and the vexed question to be thrust before her, perhaps every few weeks, whether she or her servants shall rule. There is but one answer to this question. It will be the one that knows the most. So, if the true housekeeper has not learned before marriage, she will begin as speedily as possible to perfect herself in all things pertaining to the comforts of home; so that her servants will not have occasion to reply to her, as an old colored servant said to the writer once many years ago, when asked to perform some service—"Laws now, what do you know—you're nothing but a child."—Probably the first discouraging trials will be with the cooking, for the ideal and the real in this department are far apart. Cook books are showered upon us and are good and useful, many of them; but they only tell how to do, and not why so many fail. There is comfort, and truth too, in the proverb—"Every failure is one step toward success"—and determined effort to make any one dish perfect, will generally accomplish it. Let us see the reason of some failures in preparing a breakfast. It shall be a simple one: coffee; fruit in its season; oatmeal; fish balls dropped, and muffins of rye and graham flour. These may all be delicious or wretched. We will suppose they do not come up to the expectation of the cook, and will see why. The coffee should be clear, and of distinct flavor. It is muddy and bitter with grounds in the bottom of the en-pwell, it was made of coffee ground at the store. It should be bought in the kernel, and burnt, or at least, ground at home. You know then that it is pure. It was not settled. It should have had half an egg with the shell, broken into the grounds, and a spoonful of cold water stirred with them before adding the boiling water. It boiled too long. It should never boil over five minutes, then be set aside ten minutes to settle. The oatmeal is stiff and dry with husks in it. It should be smooth like blanc-mange. There was not enough water added at first. It did not cook long enough. It should boil three hours the day before, and half or three-quarters of an hour in the morning, with added water. The muffins are tough and dry. They should be so light that a touch will break them. They were mixed too stiff, and the oven was not hot enough to bake them in ten or fifteen minutes, which is the longest time it should take. The fish-balls were soggy and fat. They should be of a golden-brown, light, and no fat in them. The reason is, the fat was not boiling hot when they went in. They should cook in three minutes. All these are little things, but great things depend upon them.

ETHEL STONE.

Little Household Conveniences.

It is often convenient to boil several kinds of vegetables in one kettle. Peas, string-beans, and new potatoes cook well together. For this purpose, small bags made of coarse, thin cloth are most excellent. Make the sacks the desired size and run a string through the top. Place each kind of vegetable in a separate sack, and tie the string around the handle of the kettle, so it can be easily drawn out. When the vegetables are

cooked, hang them up by the string for a few minutes to allow them to drain. In cooking a "hoiled dinner" in the winter, a favorite dish in New England, the vegetables retain their shape better and are superior in every way when cooked in these sacks. Another article of convenience in the way of a sack is a clothes-pin bag, made after the style of a school-satchel. Make it of heavy shirting, with a flap to button over, so that the pins will be protected from dust. Make a strap of sufficient length to be worn over the neck, allowing the bag to hang down in front or on the side. Such a sack will be found very convenient when hanging out clothes, and if placed over the neck when the clothes are taken in, the pins can be easily cared for.

My way to brush the dust and cob-webs from the ceiling, is to tie a piece of old clean cloth over the broom and draw it across the ceiling. It removes the dust much better than can be done with the naked broom, and without the danger of the ceiling being soiled. In one corner of my kitchen is an old, small-sized table, with several inches of the legs sawed off. It is called the "children's table." It is there my little girls took their first lessons in kitchen work. It is very useful in teaching them to do such work as ironing, washing dishes, etc. I find it convenient also for my use, where I can do a great deal of work sitting down, that would have to be performed while standing if a higher table was used. Where a person is afflicted and not able to remain long on the feet, much of the work can be performed while sitting, if such a table is used. **NELLIE BURNS.**

A Combination Closet.

E. E. REXFORD.

I was much pleased with an arrangement seen at a friend's, consisting of a closet or cupboard built into the partition between the kitchen and dining-room. The closet, *a, a*, projected about eight inches into each room. The leaves, *c, c*, opened to form a sort of table for receiving dishes, food, etc., and left a large opening, *e*, for the passage of food, dishes, etc., between the two rooms. Below the projection into each room was ten or twelve inches, and this space was filled with drawers, *d, d*, which could be pulled out into either room. They were used for table-linen, napkins, doyles, etc.

A PARTITION CLOSET.

The upper closet or cupboard contained shelves, with glass fronts for china, glass, and silverware. There were four or five of them, each about eighteen inches wide, and three and a half feet long, affording shelves enough for an ordinary family. The washed dishes could be set in from the kitchen side, and taken out for the table from the dining-room side, thus saving time and many extra

steps. Two slides at each end, when drawn out, support the turned down leaves. When these leaves were closed, the closet occupied but little space, and had the appearance of a book-case. The one described had ground glass in the lower half of the sash doors. In front of the upper shelves on the dining-room side the upper half had clear glass; the glass doors on the kitchen side being lined with red, the silver and glassware showed to good effect against this background. The china, etc., occupied the lower shelves. The closet could not have been expensive, and the lady of the house assured me it was wonderfully convenient, and a great economizer of her time and work.

The Housekeeper who is a Philosopher.

AMELIA H. BOTSFORD.

Reasoning upon the really essential material needs of her family, she reduces the number to three, shelter, food and clothing, and first provides for these in the best possible way. If able to select her home she chooses one warm in winter, cool in summer, convenient in arrangement and especially one in a healthful locality. She will care more about good drainage and proper ventilation than for Queen Anne piazzas and ribbon flower beds. She will not desire a house too large for her family, considering that the more room, the more work; and if dependent on her own skill and strength to keep the home in order, she will eschew elaborate furnishings and delicate and fading colors in hangings and carpets. She will buy substantial furniture to avoid frequent renewals and constant repairs, and that as light as its purpose admits to save strain in lifting and handling. She will remember the labor of dusting, and the fading effect of sunshine when tempted to buy fancy carved work and delicately tinted upholstery. There will be system in her management, with a careful subordination of routine to the comfort and happiness of the family. She will not follow a set of rules rigidly, but adapt them to the variations of climate and the reasonable desires of the household.—Understanding that the object of eating is to nourish the body, and not merely to gratify appetite, she will study what articles contain the most nutriment in the most easily digested form: and with due regard to the season will not furnish heating food in summer or a too restricted diet in winter. Her meals will be provided regularly, at proper intervals, to allow the digestive organs suitable periods of rest, and the food will be well cooked and abundant. She will not load her table with indigestible dainties though all her neighbors may; and will waste little time and strength in making cake and pies. She will not be ashamed to have it known that breakfast lacks coffee and doughnuts, that dinner is served without pie, and supper without cake; that her children have a simple repast of bread and milk, or of bread and butter and fruit, or of baked potatoes with milk, convinced that such a meal is better in every way than one more elaborate, one taxing her time and strength to prepare and resulting in a cross, sickly family. She will not be famed for her cakes at church socials, nor importuned for fancy recipes; on the contrary, the neighbors will probably pity her husband because his wife isn't a "good cook." But the babies will be rosy and happy, and the mother will have time for a daily walk, or even to sit down and read by daylight!

She will, of course, provide suitable clothing for the family; and on this point will decide that health and comfort are to be secured at any sacrifice. Each member of the household must be clad with reference to changing seasons. Thin stockings will not accompany heavy cloaks, or exposed throats go with velvet drapery. Every garment will fit loosely enough to insure ease, but be finished in a workmanlike way; the material will be durable and pretty, without being at all striking. As the "philosopher" would avoid wasting time and labor on what would soon be worn out, or discarded as unfashionable, she will avoid the whim of an hour and the extreme of fashion. She will not sanction large expenditure for dress or trimming

so elaborate as to require much time and patience. She will consider that to devote the entire energies of a human mind to the subject of dress is a thing that is certainly unworthy of any true woman.

In brief, the philosophic house-keeper has courage equal to her convictions. All, doubtless, would admit that the larger portion of woman's work is not absolutely necessary; but only a philosopher will be able to forever forego the common ambition of "having things like other people."

Convenient Coal Box.

Make the box of any size and form, to contain the coal to be kept, and to fit the place it is to occupy in the wood-shed, cellar or elsewhere, by nailing boards around four corner pieces of scantling, strong enough to bear the weight. Set the bottom to slant towards the front to throw the coal to the opening, which is closed by a board sliding up and down behind two halved strips, nailed on each

CONVENIENT COAL BOX.

side of the aperture. The corner pieces project as legs, leaving the front bottom of the box high enough to easily set a coal-scuttle under it.

Waste from Well and Cistern Pumps.

The drip, and the waste water when several pails are taken out to get down to cool fluid, should never be left to form a "mud puddle" which is unsightly; and the impure water is likely to run back into the well or cistern. Ten minutes' work will nail together a couple of boards in the form of a *V* of any needed length, which set at a slight incline will carry all the surplus water away. It is perhaps better to set a low box eighteen to twenty-four inches square directly below the end of the spout to place the pail into, and run the *V*-shaped trough from the outer side of this. Better still is a square underground brick drain, or a tile one, or one made by nailing four narrow boards together; the last-named is less durable, but will suffice for two or three years. Keep it dry around the well.

THE EYES.—For any serious trouble with the eyes, of course a surgeon or oculist should be consulted. Those who read much should be very careful as to the light, which should come from above and over the left shoulder. Gas often flickers and is unsteady, and is much inferior as a light to read by, to a good kerosene lamp. Many with weak eyes have found great benefit from giving them a cold bath the first thing in the morning and the last thing at night. Hold the face in a basin of cold water a few minutes, remove the face from the water with the eyes shut and afterwards gently dry them with a soft towel without irritation.

An Unexpected Journey.

AGNES CARR SAGE.

The great cherry tree in Deacon Dodge's front yard was bending beneath a luscious burden of red and yellow fruit, and Charlie Dodge, perched on the highest rung of a tall ladder was rapidly filling a large basket with the juicy Ox-hearts. He looked anything but happy this sunshiny summer morning, although the birds twittered gaily in the green branches around him, and every fifth cherry popped into his mouth instead of the basket. "It's a downright shame," he grumbled, "to keep a fellow at work on the Fourth of July, and I wish all the cherries were in Jericho."—"Never mind Charlie, boy," said his mother, who had come out to secure some of the fruit for a pie, and overheard his complaint. "You know it is only because your father was called away unexpectedly, and he is afraid rain and birds together will make havoc of the cherries if they are left a day longer. Be spry and you will be able to go to town and see the fireworks this evening." She returned to the house, and the lad was left once more alone, but not for long. A whistle sounded down the road, and a merry voice sang:

"Squeak the fife, and beat the drum,

Independence Day has come."

And then, as Charlie's freckled face suddenly appeared, framed in green leaves, two boys came to a halt and called, "Hollo, what are you doing up there! aren't you going to town to see the celebration?"—"I can't," sighed Charlie. "Pa had to go to Dorchester, and left me all the cherries to pick before night."—"Glad I'm not you then, for there is to be great sport in the Park, a greased pole, hurdle and sack races, and at three o'clock a woman is to go up in a balloon. Wish she'd take me with her. But why can't the cherries wait until to-morrow?"—"Father thinks it will rain to-night and spoil them."—"Nonsense! there isn't a cloud to be seen," and Jack Martin, and Bobby Button turned their faces up to the sky, which was indeed "deeply, darkly, beautifully blue," without a speck to break the clear expanse.—"I think so too," said Charlie climbing out on a limb, and tilting up and down, "and oh! I do want to see the fun awfully."—"I tell you what," suggested Jack, "you come with us and see the sport, and we'll come back with you at four o'clock and get all the Ox-hearts gathered by dark."—This was a generous offer, but Charlie hesitated. "I don't know," he said, "I'm afraid pa would'n't like it, and the robins are so saucy and greedy they eat up all the best ones."—"My teacher says they

deserve their share for killing the worms," said Bobby, "and just think all you will lose. Every one is going, I don't believe there will be another boy left in Pinville."—"Will you be sure and come home at four and help me?" asked Charlie, sorely tempted.—"Yes, sharp!" said Jack, "so throw us down a handful of your bothersome cherries and come along, for it is getting late.

Thus urged, Charlie filled his friends' and his own pockets, and without telling his mother his intentions, slid down the tree, and was soon trudging along the dusty road toward the county town some three miles distant from Pinville, the rural village where the trio lived. It was a warm day, but the highway was gay with merry parties in holiday attire, and as they entered the town, the music and firing was almost deafening. Houses were patriotically decked with flags and banners, masqueraders in quaint costumes as the "boys of '76," amused the spectators, and by the time the main-stand on the green was reached, from which the chief man of the place was to read the "Declaration of Independence," Charlie had forgotten everything except the enjoyment of the hour. But he was both surprised and annoyed to suddenly discover that his mother's little pet dog Mab had followed him, and now came crouching to his feet, sure that she was too far from home to be sent back. "What a bother," he exclaimed, but Jack just then called his attention to a gaunt female in a linen duster,

loon, which looked like some huge brown monster pinioned to the earth. "The car looks comfortable," said Charlie, "and I see a stock of provisions have been laid in for the voyage."

At that moment a bell struck quick and sharp upon the air, the cry of "Fire! Fire!" resounded on all sides, and a sudden rush of the crowd made Charlie hastily seize Mab and tuck her under his arm, for fear of trampling. It is marvellous how quickly a mass of people will collect, and how quickly they can disperse, and in five minutes the park was almost deserted, except by the three friends. "Only a barn or a hay-stack," said Jack, "let us stay here, and have a good look at the balloon." And as an engine went thundering by, followed by a stream of men, women and children, Bobby climbed unobserved into the wicket-car and seated himself on the cushioned seat.

"Up in a balloon, boys, up in a balloon," he sang, "come in and let us play we were on our way to Cloudland."—"Cloudland, sure enough," said Jack, glancing up to see that the sun had disappeared, and the sky was dark and threatening. "Why! all the blue is gone, and the wind is rising, we shall have a gale."—"Oh, the cherries!" cried Charlie in dismay, but the thought did not prevent his stepping into the aeronaut's basket to see what it was like. Jack was a mischievous chap, and thinking to give his friends a scare, slyly cut one of the ropes and began swaying the enormous ma-

"UP IN A BALLOON, BOYS."

Drawn and Engraved for the American Agriculturist.

with a green veil tied over her bonnet. "See, that is the balloonist," he said "isn't she a guy?"—"Yes," put in Bobby, "but she's smart, and knows what she is about. She gets fifty dollars for her airy trip. And may lose her life."—So the lads wandered on, with Mab at their heels, listening to the Spread Eagle speeches, laughing at the efforts of some country clowns to reach the ham on top of the well-greased pole, popping cherry stones at every cat brave enough to venture out on the "Glorious Fourth," and investing their small stock of pennies in lemonade highly flavored with molasses, until at length they came to the bal-

chine back and forth. Both started up in affright, but were soon laughing at the joke, and rather enjoyed the motion.—"I wish we could go up a little way, and be pulled down again," remarked Bobby, when, even as he spoke, a fierce gust of wind—such as sometimes arises in summer—suddenly swooped down upon them, struck the balloon until it shivered like an animal in distress, and before the boys could realize what had occurred, the remaining fastenings were snapped, and with a bound that threw them from their seat, the brown ball flew up like a wild bird let loose from its cage, stopped, wavered, and then began once more slow-

ly, but steadily to ascend.—“Let us out, let us out,” screamed Charlie, struggling to his feet, but already the earth was many yards below, and he saw Jack’s horror-stricken face as he tried vainly to clutch the hanging ropes. Bobby would have jumped, but Charlie held him back, and poor little Mab whined piteously, as she was tossed from side to side by the swaying motion, and the ship of the air with its youthful passengers flew relentlessly upward and onward. “There is no help for it,” gasped Charlie at last, sinking back white and trembling, “we are off for Cloudland and no mistake.”—“But what will become of us?” asked Bobby, struggling manfully to keep back the tears as he watched the crowds below fade into tiny specks, the friendly houses and trees, and even the flames of the burning building disappear in the distance.—“I don’t know,” groaned Charlie, and oh, how he wished himself back in the old cherry tree, while the faces of his father and mother rose reproachfully before him.

“It was Jack’s fault for cutting the first rope,” said Bobby, “and the others could not have been securely fastened.”—“We ought never to have gotten into the car,” said Charlie, “and here comes the rain.” Sure enough, they had entered a wet cloud, and were drenched to the skin, but as they mounted higher the sky became clear, although they could see it was raining beneath them. They were above the clouds which shut out the earth like a heavy fog.

“It is sort of fun, too,” exclaimed Bobby, becoming exhilarated, “like flying, and how small everything seems.”—“Fun I don’t fancy,” said Charlie, gloomily, “and the trouble is we don’t know where we may come down.”—“In Europe, or Africa, maybe,” cried Bobby, rather pleased at the idea.—“In the ocean more likely, to be drowned and eaten by sharks, and I think we are descending now. Throw out a second bag,” They did so just as they skinned the top of some forest trees, which made the car careen so they had to cling to the sides for dear life.

On they went, sometimes one way, sometimes the other, as the various currents of air struck them, now in danger of being dashed to pieces against some tree or rock, now floating out of sight of human habitation, and it seemed as though they must have travelled hundreds of miles by the time they saw the sun set in crimson and gold, and the stars come out in the blue vault above.

“I am hungry,” said Bobby, and then he thought of the box of provisions. “Madam Green Veil will have to give us her supper to-night,” and he drew out a couple of sandwiches, one of which he pressed upon Charlie, who, however, was too forlorn to eat, bitterly regretting his disobedience, and clasping the dog in his arms, murmured: “Oh! Mab, poor Mab! shall we ever see home again!”

There was no moon, and the darkness settled down thick and dense. It was useless to look out any longer, and at length overcome with dread and homesickness, the two boys said their prayers, and sobbed themselves to sleep; while beneath the cloudy sky the frail bark drifted on without guide or ballast, truly at the mercy of the winds. It must have been about midnight, when a severe shock awakened each lad with a frightened scream, to find themselves once more at rest. The balloon had come to a standstill, but where? “We are in a tree or in a jungle,” said Bobby, putting out his hands and feeling in the darkness.—“For here are leaves all around us, and the ropes seem to be caught in the branches.”—“Shall we try and reach the ground,” asked Charlie, “the balloon may fly off with us again.”—“No, I guess its gas is pretty well exhausted. Better wait until daylight, or we may land in a nest of cannibals or rattlesnakes. We may be in Japan, for all we know.”—Mab began to whine, but was quieted with a piece of meat, for fear of awaking the savages or beasts of prey, and shivering with cold in the chill morning air, the boys sat imagining all sorts of horrors. For to their excited imagination every rustle was a venomous snake, and every shadow a crouching foe, while minutes seemed hours, and they could hardly believe it was but yesterday they had seen

Jack’s terrified face gazing after them in fright and amazement as the balloon left the park.

At last the day dawned, and with it a great and wonderful surprise; for as the light revealed surrounding objects, they rubbed their eyes and gazed at each other in mute astonishment. A tropical scene, with palms and cocoanuts, and dusky forms, would not have amazed them half as much as did the reality, when they discovered that they were not in Europe, Asia, or Africa, but anchored safe and firm in the leafy boughs of Deacon Dodge’s favorite cherry tree.—“Is it a dream?” ejaculated Charlie, staring at the old stone-house, the familiar well, and the juicy Ox-hearts, now discolored and cracked open by yesterday’s storm. The collapsed balloon forbade that, however, and now Mab’s joyful barks brought Jack Martin tearing from the house, to shout and hurrah in an ecstasy of delight and welcome. When they once more touched the earth, Charlie felt as though he would rather meet a band of savages than his anxious pale-faced parents, who now came hurrying to meet and greet them.—“Oh, papa,” he cried, “I am so sorry the Ox-hearts are spoiled, and you may take my rifle, and all that I have to pay for them.”

But the good Deacon only sobbed as he clasped his son in his arms.—“My dear boy! I am sure you have been punished enough, and I care for nothing since you are safe at Cherry Farm.”

Charlie never forgot the terrors of that night in the clouds, and though scientific men decided that the balloon went some distance west, and then, the wind veering, was blown almost directly back again; the boys scorn the idea, and are sure they travelled thousands of miles, if indeed they did not go round the world on their unexpected journey.

The Doctor’s Talks.

One of my young friends asks about “Monkey’s Bread,” a fruit which he has seen mentioned in some book. Monkey’s Bread is the fruit of a tree better known as the Baobab tree, a native of the western portions of Africa, and known to botanists as *Adansonia digitata*. The tree is noticeable for the great size of the trunk in proportion to its height. Trees with a trunk thirty feet in diameter are only about seventy feet high. The tree is also remarkable for the great length of its branches and of its roots. The shape of its leaves, and of its very large white flowers is shown below in figure 1. The fruit, also shown, is sometimes a foot in length, and has within a mealy pulp, which

Fig. 1.—THE MONKEY BREAD.

is mixed with stringy fibres; it has a very pleasant sour taste, and is eaten not only by monkeys, but by the people, who usually eat it with sugar, which the monkeys doubtless do not add.

I was reading the other day of the manner in which the English bumble bees injure the bean crop. The bean most commonly cultivated in

England, is a kind seldom seen in this country. It has a tall, straight stem, with long flowers in little clusters. These flowers are too long for the bee to enter the usual way and reach the honey, as its

Fig. 2.—BUMBLE BEE CUTTING FLOWERS.

tongue is too short. The bee wants the honey, and failing to get at it in one way, he does just as you would do—he tries another. Knowing that there is honey at the bottom of the flower, the bee cuts a hole through from the outside, and reaches the sweets by a short cut, as shown in figure 2. This is very “cute” on the part of the bee, but had for the farmer, as the pods from the blos-

Fig. 3.—DEATH’S HEAD MOTH.

soms thus injured, seldom ripen. Some farmers pay boys to hunt for and destroy the bee’s nests, while others think that, on the whole, no great harm is done, as a portion of the pods are not injured, and these grow all the larger for the thinning.

YANKEE BEES AS SMART AS BRITISH.

It is not only the English bees that make use of this trick to get at the honey, but our own bees do the same. The beautiful Rocky Mountain Columbine first came into cultivation a dozen or more years ago; its great beauty is due, in part, to the very long spurs to its flowers. One morning I discovered the flowers, upon my only plant, in a miserably bedraggled condition. On examination, I found that each spur had a small hole near its end. What could have made it? When more flowers opened I was early on the watch, and found that the bumbles, failing, so to speak, to enter by the front door, and reach the honey at the bottom of the long spurs, broke in at the rear, and like sensible bees, cut a hole through which they could reach the honey with their tongues without trouble.

“HOW CAN I KNOW THE DEATH’S HEAD MOTH?”

This is a question that has been more than once asked of me, the questioners not being aware that this is an European insect. The caterpillar is very large, and in Europe feeds upon the potato plant, just as our great green Potato-worm—more frequently called Tomato-worm—does in this country. The moth, (figure 3,) the largest in Great Britain, has a spread of six inches; its wings are brown, marked with yellowish and black. The back of the moth is black, and on its chest there is a marking in light yellow, which closely resembles the picture of a skull. In Europe the ignorant people, while not at all afraid of the caterpillar, which does all the mischief, have many superstitions about the moth. Its appearance in the house, especially if it flies against and puts out the light, is thought to foretell serious illness or death.

Many a Slip twix't the Claw and the Lip.

In a feathery grove of waving seed-weed, at the bottom of the deep blue sea, a Smooth and a Spiny lobster, met one day, with angry looks and bristling claws. A feud had long existed between the two families to which these lobsters respectively belonged, but to-day a fresh quarrel had arisen, and it occurred in this wise.

During a morning stroll for the good of his health, the Spiny lobster had suddenly come upon a sheltered nook, in which lay a large fish which had died a natural death, and for some reason had

like you, who are not much better off in your family relations than a poor miserable crab?"

"Just as you please," retorted the Yaukee, enraged by this taunt, "but you will have to fight for your dinner if you want it," and he waved his mammoth claws menacingly, with a scornful glance from them to the small delicate extremities of his opponent, standing in rage before him.

Spiny-back drew back a pace, "I discovered it first," he faltered, "and by right it is mine. If we took the matter before a judge, I feel very confident he would decide against you."

"But I have it," and the two lobsters glared at

Can You Talk with the Pencil?

If I had asked, can you draw? you would not perhaps have been so much interested. Yet drawing is in a great measure talking with the pencil. If one asks the way to a neighbor's, or to the next village, you can reply by using paper and pencil in a manner that will be more useful than mere words. You will start with the point where you are; direct him to take the next right-hand road, to take the next left-hand turn, after passing a large elm tree, and after crossing the bridge to keep straight on. All these points you can make upon the paper, and

A DISPUTE AT THE BOTTOM OF THE SEA.

Engraved for the American Agriculturist.

escaped the notice of the monsters of the deep. Delighted at the discovery of this unexpected treasure, Mr. Spiny-back hastened home to summon his family of children—comical little fellows, some six inches long—to a feast, and picnic in the seaweed grove. What was his wrath and disgust, when, upon his return, he found an American or Smooth lobster in quiet possession of the prize, and evidently about to bear it away to his favorite crevice in the rocks, and there enjoy it with his own particular friends.

"See here, sir," shouted Spiny, with great pomposity, his long feelers trembling with excitement, "that is my property, and I was coming with my family to feast upon it in the shade of yonder algæ. Please then to immediately drop that fish, and retire at once from our company."

"So ho!" cried Mr. Smooth-back, evidently feeling "that possession was nine points of the law," "there are two sides to that question. I just found the fish myself, and certainly shall not give up the prize at your unceremonious command."

"Do you know who I am sir?" growled the Spiny lobster, his pop-eyes standing out farther than ever. "I belong to the great *Palinurus* family of Europe, many of whom are giants, and weigh from fifteen to twenty pounds each. We too, were highly prized by the ancient Romans, and shall I yield to a common Smooth-shelled lobster

each other so ferociously, that all the little Spiny's ran off and hid in a perfect panic of terror.

"Why don't you cut it in two, and each take half," suggested a Solomon-like oyster, who had been a silent listener. But the crustaceans were too angry to heed, and crying, "all or none!" one seized the fish by the head, and the other by the tail, and tugged and fought until the water foamed and boiled around them. The European sacrificed half of his antennæ, and the American lost one of his large claws, which, imposing as they appear, can be knocked off with a very gentle blow, though fortunately for Mr. Smooth-back new ones will grow out again in time. Hot and furious the battle raged, and they might have ended like the Kilkenny cats, if a sudden clap of thunder had not caused each to spring at least a foot from the ground, for lobsters are all peculiarly sensitive to these thunder and lightning shocks, and as peal after peal continued to shake the earth and sea, forgetful of enemy, dinner, and all, except their unreasoning terror and desire to escape, the Smooth and the Spiny lobster each scrambled off to his hole, while a big fish that had lain quietly awaiting its chance, swallowed the bone of contention, greatly to the amusement of the wise oyster, who chuckled in his shell, and whispered to his wife—a fair, white pearl, "Ah! there's many a slip twix't the claw and the lip."

the inquirer, if he forgets your directions, can look at the sketch and be sure he is right. So, if you are about to build a rabbit hutch, or a bird house, make a sketch of it, that is, say upon paper just what kind of an affair you will build. If it does not quite suit you in some parts, rub out and draw anew, for it is much easier to make alterations in your house on paper than it is in the thing itself. Then having fixed upon the size for the house, mark down the figures, and you will be pleased to find how much easier it is to build, if you have the sketch at hand to tell you how. "But I can't draw"—Did you ever try? The first lesson you need is, to draw a straight line. Try to draw a horizontal line about two inches long, without the use of a straight-edge or ruler. If not straight at first, try again, and keep trying until you can make one that is fairly straight. Then make another line about a quarter of an inch from the first, and then others, all an equal distance apart. Next try perpendicular lines in the same manner. A few lessons in drawing lines, horizontal and upright, making a number of both at different distances apart, but all of each set at equal distances, will be very useful in educating the eye and the hand. You can also try drawing long lines, others one-half as long, and so on, first making the length by your eye, and then applying a measure. These will be capital exercises for odd times. T.

OUR RECORD OF Recent Agricultural Inventions.

Corn Planter, Check-Rower.—A. Anderson, Galesburg, Ill. Feb. 12; No. 293,395. This invention relates to that class of check-row attachments to corn planters, in which a rock-shaft placed transversely

on the planter, is provided with a forked lever at each end, to be swung by knots or tappets on a stretched wire, thereby giving motion to the rock-shaft, such motion being transmitted to the slide-bar used to actuate the seed measuring and discharging devices. The engraving shows the parts containing the improvement patented. The motion of the rock-shaft *d*, *d*, being transmitted through the rocking plate *k*, the sliding bars *i*, *i*, and the oscillating bar *h*, to the planter seed-slides by suitable mechanism not shown. The claims of the patent embrace only the combination of the parts shown.

Horse Rake.—J. M. Clark, Greeley, Colorado. Feb. 5; No. 293,998. The inventor claims as new, the combination with the lever *z*, and chain or rod *g*, connected to a forward moving pawl, of the spring-catch *j*, and bell-crank lever or treadle *k*, pivoted to the frame-

work of the rake, in position to adapt it with the spring-catch to move in an oblique plane, so that it may be operated by the driver's foot to bring the parts above named into action to dump the rake. The rake is held down by a forward pressure on the lever *z*.

Grain Binder.—J. H. Gordon, Rochester, N. Y. Feb. 19; No. 293,649. This patent covers two improvements. The object of the first is to sustain the overhanging end of the standard *f* of the binding-arm shaft rigidly in position, without interfering with the passage of the

grain thereunder, which end is attained by the form and position of the braces *b*. The second part of the invention provides a kicker or ejector, which projects outward immediately below, and beyond the edge

of the table, thus ensuring the delivery of the bound bundle, and preventing the bundles from clinging to each other, and being carried by the machine. These improvements, shown in section in the engraving, apply particularly to the machines previously patented by the same inventor.

Potato Digger and Ridger.—B. W. Binford, Richmond, Va. Feb. 12; No. 293,403. This invention is designed for preparing ground for planting potatoes and root crops, for covering and cultivating such crops, and for digging them when matured. It consists broadly of a cart from the axle and main frame of which is suspended a frame carrying adjustable plowing and digging attachments. This frame is so constructed as to

be raised by backing the machine, suitable means being provided for holding the frame at any desired elevation. The engraving shows the machine with attachments for harvesting. When wanted for planting, the inclined plate *k*, and the grating *n*, are removed, and the standards *i*, are provided with plow points and tilling boards.

Harvester Reel.—Walter A. Wood, Hoosier Falls, New York. Feb. 26; No. 294,103. The object of this invention is to simplify the mechanism by which the

operator in his seat on the machine, controls the position of the beaters in striking the grain. The invention consists in the means used to secure the operating lever in different positions at the will of the operator. The reel-shaft supports the beaters, and takes its motion from the bevel-wheel. On an iron plate bolted to the reel-support is pivoted the operating lever by a bolt, which is adjusted to engage certain perforations in the lever-supporting plate, thereby varying the inclination of the beaters as desired.

Ditching Machine.—J. T. Fitzpatrick, Monticello, Ohio. Jan. 1; No. 291,043. This machine comprises the truck-wheels and frame, the plow, *e*, the regulator-wheel *g*, the cutter-bars *k*, the scoop *l*, the endless

apron, *j*, for carrying the dirt to the delivery apron *m*, and the adjustable support *t*, together with the means for adjusting gearing, and operating these parts. The operation of the machine will be readily apparent from the engraving.

Threshing Machine.—A. T. Hawley, Alton, Ill. Feb. 5; No. 292,019. This invention aims to secure the more complete separation of grain from straw, by em-

ploying two beaters working in opposition. Adjoining the threshing cylinder *a*, and oppositely revolving is a heavy beater, which throws the straw upward against the guard *d*. Above and behind the heavy beater, is a light beater, which strikes the straw as it is falling from the

guard. The wings of both beaters are ironed and armed with spikes. The engraving shows a longitudinal section of a portion of a thresher containing these improvements.

Harvester.—C. S. Stickle, Pekin, Ill. Feb. 5; No. 293,202. The aim of the inventor is to improve the means for lifting and lowering the forward portion of a "header," that is the portion which carries the sickle

frame, together with those for adjusting the elevator frame, and operating the elevator. The engraving shows a plan view partly in section, the elevator frame and the arms of the reel being removed. The claims of the patent embrace the bars *f*, *f*¹, *f*², and *k*, upright standards carrying adjustable bearings, and secured to the bars *f*; the transverse bar *a*, with a fixed bearing, and short independent axles in *a*; the tongue *b*, and various attachments thereto.

Threshing Machine.—A. J. Hoag, Battle Creek, Mich. Feb. 19; No. 293,876. The inventor's aim is to provide more efficient means for separating grain from its straw. To this end he provides mechanism for holding the fingers at different inclinations with respect to the beaters; also special grating-bars, for facilitating

the escape of the grain to the lower shaker, and means for adjusting the grating-bars in relation to the beaters. The engraving shows the improvements applied to an ordinary threshing machine of the vibrator class, the inclosing boards being removed.

Huller, Cleaner, and Separator.—W. W. Jackson, Bethany, La. Feb. 5; No. 293,029. The inventor claims as new in this pea or bean huller, the

combination of the fan, the inclined sieve, the rotary toothed hulling cylinder, the stationary toothed case with openings for the discharge of grain and trash, as shown in the engravings.

Cockle Separator.—J. M. King, Rochester, Minn. Feb. 5; No. 293,039. This cheap and simple separator, is said to be rapid and efficient in action. It comprises suitably inclined bottom and side boards, cross-

bars *a*, *a*, guttered bars *e*, *e*, to serve as detents, the screen *g*, held in the gutters, and smooth plates of metal *k*, to facilitate the movement of the grain to the screen. The cockle finds a way out through the opening *h*.

A Fine Milch Cow.

We herewith present a portrait of a pure-blooded Ayrshire Cow. "Duchess of Smithfield" is a fine specimen of a comparatively modern but very hardy and useful breed of cattle. She is a perfect type of the famous Douglas family of Ayrshires, and has taken first prizes at State Fairs since 1879. With a record of nearly nine thousand quarts of

The show consisted of breeding animals of the numerous classes, as well as of useful ones. Thus there were several classes each of Thorough-breds, Arabians, Trotters, Roadsters, Horses-of-all-work, Heavy Draught, Clydes, Normans, Coaching horses, etc., numerous classes of driving horses, as carriage horses, "T-cart" or "Dog-cart" horses, "Cobs," Ponies, Coupé horses, Four-in-hand teams, etc., Saddle-horses, Cobs, Ponies of all sizes

The smallest full-grown one was the seven-year-old mare "Midget," standing only nine and a half hands high (thirty eight inches). The dividing line between ponies and cobs seems to be fourteen hands or thereabouts. "Cobs" are pony-built horses, above fourteen and under fifteen hands high.

There was an astonishing disparity in size between the little fellows of nine or ten hands, and the enormous draught horses which were shown in their classes. There were not many entries of these, but they made up in bulk. One gray mare stood eighteen and a half hands high, and weighed, it was said, nineteen hundred and sixty pounds; a gray gelding of four-years-old, was seventeen and a half hands high, and weighed eighteen hundred and fifty pounds. A dapple-gray Norman stallion, "Marquis," shown by H. G. White, of Syracuse, sixteen and a half hands high, and weighing eighteen hundred pounds, was by odds the best stock horse of the heavy ones.

There was a small but choice show of coach stallions, a class of horses which it will pay farmers to patronize if they have large, sound, well-formed mares. Among these were two French stallions of large size and wonderful grace and beauty of form and action—"Tyrolien" and "Telesphare," belonging to W. S. Gurnee, of New York. The Arabian stallions, presented by the Sultan of Turkey, to Gen. Grant, were the only pure Arabs shown. Fine specimens of strong blood.

The growing love for the horse, and for the manly sports which center about him, is becoming both a fashion and a passion with our rich men, and it certainly should be in every way encouraged as likely to produce lasting benefit to the country in many ways. America may well feel proud of her trotting horses. Let us try to produce a breed of good walkers.

A FINE AYRSHIRE COW.—Drawn and Engraved for the American Agriculturist.

milk in a single year, on moderate feed, and without forcing, she stands high among the list of great milkers. Her grand udder measures sixty-eight inches in circumference, and indicates, better than words can express, the great capacities of the animal as a producer of milk. The average Ayrshire cow may not be chosen for her beauty, but the constitutional vigor, great milking powers, and the general air of business shown in the picture (from a photograph by Schreiber) must inspire any lover of true bovine worth with more than thoughts of profit. This cow very thoroughly combines the good qualities of a superior milch cow. We wish her tribe may increase among our dairy farmers.

The National Horse Show.

The second National Horse Show held in Madison Square Garden, in the City of New York, was, like the first, gratifying to its promoters. There was a fine display of horses, of which we shall print engravings in the future.

The "Garden" is really an amphitheatre, capable of seating some ten thousand persons, and of accommodating as many more. Within the oval arena, well covered with tan-bark, half a dozen or more four-in-hand coaches may be driven at once, while around the sides of the great building, occupying an entire city block, excellent stalls and loose boxes were arranged for the comfortable accommodation of the horses. The premium list was very full, and the prizes attractive, varying from twenty-five to five hundred dollars each, the same animal being permitted to enter for two or more prizes in different classes.

If there is any one thing which is discouraging to lovers of horses attending the State Fairs, it is the fact all the best animals are shut up and locked in dark stalls, where it is almost impossible to get a sight of them at all, except through the special favor of their keepers. Here all the loose-boxes were slatted, so that their occupants could be distinctly seen, and the horses in the stalls, when not eating, were almost uniformly tied heads outward by two hitching reins, so that even vicious horses could not bite.

shown under saddle, Hunters, those entered for jumping, besides trained fire-engine horses, Police-horses, Cavalry horses, etc.

All these classes, one hundred and twenty-one in all, in which there were entries, were exhibited and judged in the arena before the assembled multitude, who were free to express their approval by applause or otherwise, when the ribbons were awarded. Popular judgment in such cases is usually very just, and it requires good judges to independently brave the disapproval of the crowd.

The impression made by the banded and docked horses, the grooms, the footmen and drivers in livery, the tights, top-boots, etc., and the vehicles of all sorts of strange and useless forms, was much as if a piece of "Rotten Row" or "Pall-mall" or some other fashionable part of London had been imported to New York and put on exhibition as a sort of after-clap to the walking matches and other great shows, which occupied the same arena a few days before.

Nevertheless as England really does lead the world in horse matters, especially in the use of the horse as an article of luxury, why should we not imitate her, and if need be, import English horsemen to show our rich young fellows who want to ride to hounds, to chase foxes (or scent-bags) across the country, to drive four-in-hand, tally-ho coaches, and all that sort of thing, how to do it all in true cockney style on American soil.

The most numerous impressive classes were, as may be supposed, those of horses for pleasure and show-driving, and for use under saddle. I here include the coaching teams, and all the various carriage teams, matched cobs, pouies, etc. The hunters formed a very interesting group, having a highly thorough-bred look, being extremely muscular, very thin, greyhound-like, and usually tall horses, with grand bone, large joints, and a suppleness really surprising. One of these, Mr. Fred. Gebhard's "Leo," a six-year-old chestnut gelding, sixteen and a half hands high, cleared a bar six feet six inches high, landing safely with his rider—the highest jump of which there is any record in either English or American horse annals.

Ponies were very numerous represented, Shetland, Highland, Welsh, and many other kinds.

The Turnip Fly.

The wavy-striped Flea-beetle, or "Turnip Fly," (*Maltica striolata*), is a great pest to young turnips when first breaking through the soil. If the young seedlings can be protected at this time until a few leaves form, they usually need no further care. One of the best preventives is to have the soil rich and well prepared, that the crop may push forward rapidly. Some turnip growers have found it profitable to employ boys with bags attached to curved forked sticks, which are run astride the rows of young plants. The beetles, when thus disturbed, jump into the bag and are afterwards destroyed. A common application is equal parts of wood ashes and land plaster, entirely covering the young turnip-leaves. Finely powdered air-slaked lime may be dusted on with a bottle-shaped tin dish, having holes in the bottom, and a wooden handle in the top.

A Tomato Trellis.

Some support for the tomato vines is a necessity in the garden, not only for the sake of order and neatness, but the fruit is better when kept from contact with the ground. This support may vary

A TRELLIS FOR TOMATOES.

from the simple expedient of laying brush along the rows, to a carefully made trellis, intended to be used year after year. We prefer a sloping trellis to a straight one. The engraving shows one made with wire. A trellis in this shape may be readily made by the use of stakes and poles. Drive stakes of suitable length into the ground for supports, and use any small poles that may be readily procured for the slats. These may be nailed to the supports, or lashed to them with small wire or tarred twine.

About Ticks.

The Ticks belong with the Spiders and Mites, which are now admitted as a sub-order of insects. The true insects have three parts to the body, undergo a change from a larval or grub state, and the perfect insect has three pairs of legs. The ticks and their relatives have the body in two parts, have four pairs of legs, and undergo no change. Ticks are found in all parts of the country, but are most numerous in the warmer portions. They pass the early part of their lives upon plants as vegetable feeders, and hence are commonly called "Wood Ticks." The males, when they have served their purpose, die, but the females, like the female mosquito, cannot complete their career unless they gorge themselves with blood. The female ticks, whenever opportunity offers, attach themselves to animals. While some are confined to particular animals, as the bat, others have no choice, but attack cattle, dogs, and wild animals, as deer, etc. They have been found upon snakes and lizards, and will attach themselves to man. The female has a leathery skin, capable of being greatly distended, and when she attaches herself to an animal by means of her hooked claws, commences to suck its blood and enlarges to many times her former size. The engraving represents a common cattle tick, both before and after she has filled herself with blood. The writer has seen, in Texas, cattle with dozens of ticks attached to their sides, much larger than the one here figured. He has had even a more intimate acquaintance with them, when an intense itching indicated their presence on the person. A drop of water of ammonia allayed the itching, and so disgusted the tick that she released her hold. Every humane cattle owner will rid his animals of this pest. Grease alone, or mixed with a little

WOOD TICKS—NATURAL SIZE AND MAGNIFIED.

kerosene, and applied to the parts to which the ticks attach themselves, usually where the hair is thin, near the udder, will make the locality unpleasant for these annoying bloodsuckers.

A Fence Post Axe.

An axe for making rail holes in fence posts, is shown in the engraving. It is an ordinary axe blade, cut and hammered down by a blacksmith.

A POST AXE.

The blade is of the width desired for the hole in the post. With this axe and a good post-holder, a skillful person can make the rail holes rapidly.

MORE ABOUT LAMB-KILL.—Charles Ives, of Mis-
couche, Prince Edward's Isle, writes us, with reference to an article in June last, that he has had "a wide and most unpleasant experience" with the "Lamb-kill," which grows abundantly in his locality. His object in writing is to make known what he regards as a simple and certain remedy for animals poisoned by the plant. When a lamb is poisoned, it usually cannot stand, and when he finds one in this condition, he takes it under shelter as quickly as possible. "I take half a pint to a

pint of milk, and while this is warming, I get a good sized onion, or better, a hunch of shallots (they being stronger), peel, and chop them as fine as possible. The chopped onion is mixed with the warm milk in a narrow mouthed piteher, and given to the animal, making it swallow as much of the chopped onion as possible, as that is the important part of the dose. In very severe cases it may be necessary to repeat the dose after a few hours. I do not think I have lost an animal by poisoning since I began to use this remedy, while before, I have had five or six lying together, dead."

Three-Horse Whiffletrees.

A subscriber sends us his method of arranging whiffletrees for three horses abreast. The larger eveners, *a*, is made of inch and a half plank cut with

WHIFFLETREES FOR THREE HORSES ABREAST.

a curve, so that the single whiffletree, *b*, is on a line with the others attached to the double eveners, *c*.

Increase of Rainfall in the Western States.

H. C. EWING, NEBRASKA.

In the January number of the *American Agriculturist* an article appeared, entitled "Do Trees Increase Rainfall?" which fully answered the question propounded by its title, but as the author had evidently given the subject much thought, we were sorry he did not explain or even give his views of the cause of the increase of rainfall in the Western States, particularly in the district west of the Missouri. There is great practical importance in this question to those who are making themselves homes in the broad Western States, and investing their money in that region.

As to one fact, the writer of the above-mentioned article seems to be in error. The amount of rainfall in Illinois and Iowa, instead of decreasing, as he states, has been increasing year by year, so that in sections where, fifteen years ago, the complaint was of the scant rainfall, the people now are unable to properly plant, cultivate, or harvest their crops, because of the wet weather. This is not fiction but a stern reality, as farmers in those States will testify. Nor has this increase been confined to the region east of the Missouri. A few years ago all Nebraska, west of the "Missouri River Bottoms," was considered an unproductive waste on account of the drouths, there was no rain to keep vegetation alive. But soon the western limit of the rain belt was moved to the meridian of Lincoln. So recently as 1878-9 no rain fell in that district in Southern Nebraska from August 1878 until June 1879. Wiseacres said there is no use going further west, no rain ever falls there—it was a desert and nothing would grow. But during the past three years the amount of rainfall has been gradually increasing in the meridian of Lincoln, Neb., until the amount during the year just past has been nearly equal to that in any of the Atlantic States. The wise men have been compelled to move the western boundary line of the rain belt westward successively from county to county, until now the acknowledged rain area covers nearly the whole of the State of Nebraska. Such are the facts in regard to this western advance of the rain area and so general, regular and continuous has it been that we must look for the cause, not to electrical disturbances, or spots on the sun, but to something more intimately connected with the tide of immigration and advance of civilization.

As was truly said by the writer of the above-mentioned article, the winds that bear the rain and

moisture to the western plains come from the east and south. These winds from the Atlantic and the Gulf, lose their moisture as they advance, and reach the highlands east of the Rocky Mountains almost devoid of moisture. In the days when the prairies were vast stretches of uncultivated land, the small amount of rain that did fall immediately ran from the surface into the "draws" or small creeks and creek beds, and thence at once into the rivers. The surface of the unbroken prairie was almost as impervious to the water as a bed of solid rock would have been. There could be little evaporation from the earth by the sun a few hours after a rain, for the water had run off from and not soaked into the ground. But as the land is cultivated, the rain is absorbed by the loose soil and remains a source of evaporation for several days. Some of it goes to form springs, which are bursting forth in cultivated districts where none before existed, and others, which were small and intermittent, have become strong and never failing. This change in the springs shows the increase in absorption of the rainfall by the cultivated land.

In this fact of the absorption and consequent evaporation of greater amounts of moisture may be easily seen the cause of the westward advance of the rain belt. The winds from the Atlantic and Gulf meet and carry with them the air which has been charged with the moisture evaporated from the cultivated districts, and expanding in rising over the land in its course toward the Rockies the temperature falls and rain is precipitated. The rain is, therefore, in much greater quantities than would have fallen had no moisture been added to the winds in their course. Very little moisture was added when the winds swept over unbroken prairies. The greater the amount of land cultivated each year in the eastern counties of the State, the greater will be the evaporation and consequently the greater the rainfall in the western counties. The cultivated region acts as a relay battery, as it were, adding new power to the current of wind that was almost exhausted of moisture. As the rainfall increases to the westward, the hardy farmer moves thither, breaks the land, and the rain area is moved just as much further west. Thus the process goes on, and probably will continue until the timber line of the Rockies is reached. This increase will continue in all parts of the State, as long as there is unbroken prairie to the east. We do not contend that cultivation in a district produces a greater amount of rainfall in that particular region, but we do maintain that on the western prairies, where the rain-bearing winds come from the east and south, the rainfall west of the cultivated land will be increased, and as agriculture advances so will the increase in rainfall. True as is the remark of the writer of the article referred to, that "our weather appears to be subject to important changes far beyond the reach of a forest or clover field," yet on account of the peculiar condition of this western country, and the direction of its rain-bearing wind currents, we are constrained to believe that we have herein briefly stated at least one of the leading causes of the increase of the rainfall in the Western States.

A Leaf Gatherer.

A simple and convenient device for gathering leaves from a lawn, or elsewhere, may be made by

A LEAF GATHERER.

fastening heavy cloth to two light poles, as shown in the engraving. The leaves are raked into a heap and the gatherer placed on it, after which the poles are brought close together and the leaves lifted.

Prominent Butter Makers.

There is no dissent from the decision of candid and capable dairymen, that the Improved Butter Color of Wells, Richardson & Co., Burlington, Vt., is the best in the world. Such men as A. W. Chcever, of Massachusetts, E. D. Mason, Vermont, Francis A. Hoffman, Wisconsin, use it, and recommend it as superior to all others.

BUY THE BEST AND CHEAPEST,

The Mallory Trackless Hay Elevator, Price \$5.00, is the best device in the market for filling your barn with hay. No track required, easily put up. Recommended by every one who has used it. Orders filled promptly. Send for catalogue and price list. **HERBERT BAKER, 100 Erie Street, Toledo, Ohio.**

Cuff Buttons, Watch Chains.

Watches and jewelry. Many different styles at low prices. Send for circular. **CUMMINGS & CO., 38 Dey St., N. Y.**

THE EVAPORATOR.

The Topping Portable Evaporator will dry all kinds of fruit and vegetables. Four different sizes with heater attached, all ready for use. They will pay for themselves in from one to two weeks. Here is proof:—say we take a No. 2 dryer, that dries 10 bu. per day; in 6 days, 7 lbs. to the bushel on an average, is 420 lbs. per week. At the present prices, 15 cents per lb., this is \$63.00, which more than pays for the dryer the first week in use. Please figure for yourself. Slicer, Corer, Apple, Peach and Potato Parers, Dried Fruit Presses. Send for circular.

H. TOPPING, Marion, N. Y.

THE PNEUMATIC FRUIT DRIERS.

Retain the natural fruit and vegetable flavor. The most rapid evaporation, with least fuel. Made in ALL SIZES, for farm or factory use. We also manufacture the best Evaporators for making

APPLE JELLY from Cider, without sugar or any foreign substance. Send for Descriptive Circulars and Testimonials.

(Continued from last month.)

How Watch Cases are Made.

It is a fact not generally known that the *James Boss' Gold Watch Cases* really contain more pure gold than many "solid" gold cases. The demand for these watch cases has led to the manufacture of a very poor grade of solid gold watch cases—low in quality, and deficient in quantity. These cases are made from 4½ to 10 karats, and a 5 or 6 karat case is often sold for 12 or 14 karats. It is NOT economy to buy a watch case so poor in quality that it will soon lose its color, or one so soft that it will lose its shape and fail to shut tight, thus letting in dust and damaging the works, or one so thin that a slight blow will break the crystal, and perhaps the movement. It IS economy to buy a *James Boss' Gold Watch Case*, in which NONE of these things ever occur. This watch case is not an experiment—it has been made nearly thirty years.

HAZLETON, PA., Oct. 24, 1882.

I sold two *James Boss' Gold Watch Cases* thirty years ago, when they first came out, and they are in good condition yet. One of them is carried by a carpenter, Mr. L. W. Drake, of Hazleton, and only shows the wear in one or two places; the other by Mr. Bowman, of Cunningham, Pa.; and I can produce one or both of these cases at any time.

SYLVESTER ENGLE, Jeweler.

Send 3 cent stamp to Keystone Watch Case Factories, Philadelphia, Pa., for handsome Illustrated Pamphlet showing how *James Boss' and Keystone Watch Cases* are made.

(To be Continued.)

NORTHERN PACIFIC R. R. LANDS

In Minnesota, North Dakota, Montana, Idaho, Washington and Oregon.

The Northern Pacific country is the newest region open for settlement, BUT THE RICHEST IN NATURAL RESOURCES. Its exceptionally fertile soil, well watered surface, fine wheat and farming lands, best of cattle grounds, large bodies of timber, rich mining districts, healthful climate, great navigable waters, and grand commercial opportunities are the chief attractions which invite a large population.

NOTE 10,818,433 acres or MORE THAN HALF of all the Public Lands disposed of in 1883 were in the Northern Pacific country. Send for maps and publications describing the railroad lands and the country. They are sent FREE.

Address **CHAS. B. LAMBORN,**
Land Com'r, St. Paul, Minn.

DELAWARE FARMS at low prices. Terms easy, short winters, healthy climate, plenty fruit, fish and oysters. Send for description, free. **J. D. Hendricks, Houston, Del.**

H.W. JOHNS' ASBESTOS Liquid Paints

are composed exclusively of the best and purest materials, combined on different principles from any other Liquid or Mixed Paints, and are of a higher grade than have ever before been offered to the public, either in "paste" or liquid form, and are second to none in richness and permanency of color, beauty of finish, and durability. None but the purest linseed oil and the best pigments enter into their composition.

We manufacture forty-eight standard "body" and trimming colors, beside blues, greens, reds, black, etc., and inside and outside whites, and will furnish sample sheets and pamphlets on

STRUCTURAL DECORATION
free, by mail, on application.

ASBESTOS ROOFING.

A "Fruit Tree Invigorator."

A correspondent who inquired about the medication of trees by introducing foreign substances into a hole bored in their trunks, was answered in March last. We there stated that the claim that trees could be medicated in this manner was an old one, and that we doubted if it ever had any useful application. In Bulletin No. 8, of the "Massachusetts State Agricultural Experiment Station," recently issued, we find an analysis of "The Phoenix Fruit Tree Invigorator," made at the Station. The analysis shows that the principal constituents are: Moisture, Sulphur, Lime, and Carbonic Acid, which made up ninety six per cent of the whole. The report says: "A mixture of an essentially corresponding composition, may be produced at an expense of from twelve to fifteen cents per pound at retail cost, by taking from forty to forty-two pounds of flowers of sulphur, and fifty-eight to sixty pounds of sifted wood ash."

Cures for Deafness.

Many inquiries are answered here. To begin with, before trying any mechanical appliance or any medicine for deafness, first ascertain the cause of the trouble. While a difficulty in hearing may be due to an accumulation of hardened ear-wax, or other causes that may be removed, deafness is often due to an obliteration of the ear-drum, or other derangement of the auditory apparatus, and is beyond remedy. When deafness is due to such causes, it is folly to expect relief from medicine of any kind. Audiphones, dentiphones, and other appliances to be held between the teeth, are sometimes useful as aids to hearing. These are sold at a high price, and being suited to particular cases only, cause much disappointment and complaint. A palm-leaf fan, or piece of card-board, held between the teeth, will usually answer as well as any of the "phones." Artificial ear-drums are simply impossible. Deaf persons should first consult a competent physician, and ascertain if the trouble in their case is curable.

Metal Indicators.—Divining Rods.

A letter from West Virginia asks us to send the writer at once "an instrument to hunt gold and silver, something like a magnetic needle." The superstition that certain persons were able, by means of a forked stick, to discover hidden precious metals and streams of water is a very old one. Even now, "water witching," as it is called, is practised in various parts of the country, and we have known persons of intelligence and of good sense in most matters, who think that water may be discovered by the use of a forked hazel twig, or divining rod. In the early days of California gold fever, some shrewd chaps, taking advantage of the general impression that gold and silver could be detected, offered a "gold indicator," which it was claimed would show the presence of the metal by the movement of a compass needle. Though these affairs were found to be perfectly valueless, the letter of our West Virginia correspondent shows that they are not forgotten, and the readiness with which people believe in the impossible. Iron is the only metal that will affect the magnetic needle (save one or two very rare ones), and there is no method of constructing a needle that will show the presence of gold or silver.

"Mutual Self-Endowment."

C. H. Ashford, Oconee Co., Ga., sends us a circular and writes: "I am satisfied that an expression of your opinion on its merits will be appreciated by a number of your readers, not only in Georgia, but in other States."—The document is issued by "The Mutual Self-Endowment and Benevolent Association of America." It appears that this "Association" has but little idea of the value of time or the shortness of life, when they expect people to read through eleven pages of a dull, imaginary dialogue, in order to find out what they propose. One or two pages of direct, pointed statement would serve the purpose better. The association with the long title originated at Longview, Gregg Co., Texas. It proposes to act as a life insurance company and an endowment office at the same time. The writer of the dialogue makes the scheme look plausible, but the first

and important question with regard to all schemes of this kind, is as to the integrity and the responsibility of the managers of this Association. Of this we have no means of knowing. We would not advise any one to invest in this or any other Association, until fully satisfied of its stability, and its ability to fulfill its promises. So far as Life Insurance goes, there are several companies as safe as any human institution can be, in which one can insure his life with a feeling of absolute security.

Boston Silver Ware.

Boston is the headquarters of several concerns which vie with one another in the extravagance of the advertisements and circulars relating to the silver-plated wares they offer. One circular informs the recipient that his "name has been handed to us, together with first-class recommendations," etc., a fiction to start with. These circulars are so industriously scattered that the inquiries about the Boston concerns are very numerous. One of them styles itself "The Waltham Watch and Silver-plate Company," and a correspondent in Elgin County, Ont., is very indignant that the name of a well-known corporation, like the Waltham Watch Company, should be attached to such a trashy document. One circular cautions the public against dealing "with the shop over the way," in such a manner as to lead to the suspicion that both may be parts of one establishment. One concern explains its ability to sell its wares at the very low price on account of "a secret process" used in their manufacture—which is all bosh. Cheap ware means little silver, as the purchaser will soon find out in using it. In the purchase of plated ware the buyer is entirely in the power of the seller. There are in every city dealers whose word as to the quality of the articles is a sufficient guarantee. The only safety is in buying of such dealers. The floods of circulars, the needless machinery of "coupons," etc., all needlessly increase the expenses of doing business, and the purchaser is directly or indirectly made to pay their cost.

The "K. & K."

This has not, as some might suppose, any reference to the "Kn-Klux Klan," of several years ago, but is the trade-mark of a concern which professes great things in the way of curing diseases. A correspondent at Mulmur, Ont., sends us several clippings with reference to this K. & K. concern, which has its headquarters in Michigan, and asks our opinion about it. Our opinion is, that this K. & K. affair could not carry on its business in the State of New York, or in any other State which has laws to protect its citizens from quackery of all sorts. The advertisement makes a great spread over the costly instruments owned by the concern. It is a pity that there is no law against selling surgical instruments to irresponsible parties. The K. & K. concern now propose to

SPECULATE IN CURES.

They propose to sign contracts of the "No cure, no pay" style. No physician of any standing in his profession, nor one fit to be employed, would be concerned in any arrangement that guarantees cures.

TO OUR NEWER SUBSCRIBERS.

There is nothing about which we have more frequent inquiries than about medical establishments, and medical men of various kinds. The fact that a physician advertises at all is against him, though there are some cases in which he may do so properly and legitimately. If one boasts that he has special skill in the treatment of particular diseases, set him down as a quack. If a man or concern advertises that he will perform a certain cure, or return the money if not cured, avoid the man or concern as a medical fraud.

"We Will Fight it in The Courts."

Say some makers of Oleomargarine and other bogus butter compounds, when asked their position as to the law recently passed by the Legislature of the State of New York, and approved by the Governor. This law prohibits "the manufacture of any oleaginous substance or substances, or any compound of the same, other than that produced from unadulterated milk, or the cream from the same, any article designed to take the place of butter or cheese produced from pure unadulterated milk, or cream from the same, nor shall sell or offer the same as an article of food." An exception is made in favor of pure skim cheese from pure skim milk.

THE PENALTY FOR VIOLATING THE LAW

is a fine of not less than one hundred, nor more than five hundred dollars, or imprisonment for not less than six months, nor more than one year, or both fine and imprisonment. The Act provides for a "New York State Dairy Commissioner," charged with enforcing the law.

THE GREAT DAIRY INTERESTS OF NEW YORK STATE have had a hearing by the Legislature, and a law has

been passed with full provisions for its enforcement, and dairymen in other States will watch the workings of the law with great interest. If the Oleomargarine makers propose to test the law in the courts, it is hoped that the Commissioner will give them an opportunity at once. We believe it to be a wise, just, and constitutional Act.

OUR POSITION AS TO OLEOMARGARINE,

from the first, has been, that it is not butter. If it can not be distinguished from butter, so much the worse. The whole success of these butter substitutes depends upon their sale as butter. The law requiring them to be branded with their proper names has been found useless. Now a more stringent Act, prohibiting both manufacture and sale, is passed and its efficacy is to be tested.

A FRAUD UPON THE FARMER AND HIS WIFE.

The farmer who takes all proper care in selecting his cows, and in providing them with proper shelter and food, and the farmer's wife, who prides herself upon the neatness of her dairy, and the excellence of her butter, are both brought into unfair competition with machine made mixtures of fat, which, whatever paid, so-called scientists may certify as to their wholesomeness, are not butter. The fact that were the stuff branded with its real name, not a pound could be sold, is sufficient answer to all allegations as to its quality and wholesome character—whatever the stuff may be.

IT IS NOT BUTTER.

If it could be sold for what it is, we should not object. As it is sold as butter, the law properly says it shall not be sold at all. The farmers and the purchasers are in earnest in this matter, and we are emphatically on the side of the farmers and the purchasers, and opposed to Oleomargarine and all other bogus butters with names that end in *ine*.

The Agriculturist's Microscopes.

We continue to receive the most gratifying compliments as to the superior quality and handsome appearance of the New *American Agriculturist* Microscope, which we have had expressly manufactured for the friends and workers of the *American Agriculturist*. Here are some sample replies:

NEW SMYRNA, Fla., April 30, 1884.
I have received my Microscope, and am more than paid for the money that I gave for it. It is just what I have been wanting for some time, and it is just what every one needs."
J. E. THOMPSON.

WETHERSFIELD, CT., May 20, 1884.
"I would also acknowledge the receipt of the Microscope, which came safely to hand, and is a very neat, tasty little instrument."
J. W. GRISWOLD.

ITHACA, N. Y., May 19, 1884.
"I received the Compound Microscope to-day, and after a careful examination, I can cheerfully say it is better than my highest expectations. As to the quality of work on it, the makers' name is a sufficient guarantee for that. Please therefore, accept my thanks."
I. W. SMITH.

YPSILANTI, MICH., May 19, 1884.
"The instrument exceeds anything I ever saw for the amount of money invested in it. It is certainly a marvel."
PROF. J. H. HOPKINS.

FARMLAND, IND., June 4, 1884.
"The Microscope sent by mail fully meets my expectations."
N. W. WRIGHT.

EWART, IOWA, April 9, 1884.
Please find enclosed \$1.25 for one of your Simple Microscopes. I am a subscriber to your good old journal, and have the same confidence in you that I would have in a brother. I will get up a club for your paper in some future time.
DANIEL F. WHITE.

This is the season of the year when these Microscopes can be employed to a great advantage by farmers, in very many ways. In fact, one of these Microscopes ought to pay a farmer ten times its cost every year, in the examination of bugs and insects of various kinds, which are injurious to vegetation.

The *American Agriculturist* for March, contains a full description of this new and beautiful Microscope.

If you have not this number of the paper, and would like to see the description, write to us, and we will forward it to you. This Microscope is sent, delivered free, by us, to any part of the United States and Territories for \$2—and delivered free to any actual subscriber of the *American Agriculturist* for 1884, for \$1.25. Furthermore, we will present one, delivered free, and send the *American Agriculturist* to any new subscriber, post-paid, for \$2. Still further, we will present this Microscope to any present subscriber, delivered free to him, if he sends us two new subscribers to the *American Agriculturist* for one year, at \$1.50 each.

Something for all Old Subscribers.

We are now preparing a special edition of the *American Agriculturist* for all persons who have been subscribers to the *American Agriculturist* within a period of ten years, and who are not now subscribers. This copy of the *Agriculturist* will contain matter of great value to every such old subscriber, in fact matter that he will read with the liveliest interest. Will every present subscriber, on seeing this, please notify every individual in his vicinity, who, at any time, has been a subscriber to the *American Agriculturist*, and is not now one. By so doing, he will greatly oblige the Publishers.

Getting up Clubs for the American Agriculturist.

You need not wait until winter before raising your club for the *American Agriculturist*, but begin now. Subscriptions can begin with any number. We will forward Specimen copies to every one who wishes to raise a club.

BE PROMPT, please, in informing us if there is any delay or trouble in receiving your paper, or answer to any complaints or inquiries sent us. The *American Agriculturist* goes to press regularly every month, and it should reach you on the same day every month. You will confer a favor if you will immediately write us, if there is the slightest delay in its receipt.

Progress and Prosperity.

(From the "Christian Union," N. Y., May 22.)

The *American Agriculturist* is to be congratulated on the evident signs of progress and prosperity which are found in its pages. It represents the best experimental and writing talent in the line of Agriculture in this country, and shows in all its departments the tireless energy of Mr. David W. Judd, who is now at the head of the Orange Judd Company.

Friends of Agriculture.

Mr. Lawson Valentine, who for some months has been familiarizing himself with agricultural modes and methods in England and France, visiting Lawes and Gilberts' establishment, and other interesting points, will return to the United States with a rich store of knowledge to apply to his generous acres at Houghton Farm.

Col. M. C. Weld, the "Among the Farmers" man, true to his title, is now off for a distant fortnight cruise. He goes as far north as Hamilton, Ont., and, swinging to the southward, will return with a grip-sack full of notes by the way for his host of admiring readers. Col. Weld has a great fondness for fine farm animals, and discovers more defects in a herd than most men. He, however, does not let a "good point" pass unnoticed or unpraised.

Dr. Charles H. Shine, is one of California's young horticultural men who believe they can so mingle literature with out-door life as to make it profitable in more senses than one. Among the leaders of the fruit interests in the Golden State, he left his western home and spent last year in John Hopkins' University in the study of language, to become the better able to write clearly and well upon his favorite horticultural subjects. He promises to give our readers the results of his added experience and study.

Dr. Manly Miles, Professor of Agriculture at Amherst Agricultural College, made us a pleasant call, during which we learned that he intends to spend a portion of his vacation in the Michigan "Peach Belt," studying the important subject of yellows in the peach. Dr. Miles has thoroughly equipped himself with microscopes for this difficult task, and we hope before the year closes to give our readers some more light upon a

question, that now is as dark as it is vital to the fruit growers of the Peninsular State.

Mr. A. W. Stuart, of Australia, is now visiting the United States, and studying the subject of silos and ensilage, with a view of introducing these methods of preserving fodder, into his own country, in their perfected forms. We have taken pleasure in directing Mr. Stuart to some of our most successful farmers, who are feeding ensilage almost exclusively to their large herds. It is justly a matter of no little pride to Americans, that borrowing a method from an old European country, we have so perfected it, as in a few years time to become the teachers of the whole world.

Cyrus H. McCormick, who made the first successful Reaper, has now closed his life-work at the advance age of seventy-five. It is but a little over thirty years since that strange looking machine, at the first World's Fair convinced England and all Europe, that reaping by machinery was possible. The influence of this invention upon the agriculture of this country and of the world is incalculable, and it is gratifying to know that unlike many inventors who have benefited their fellows, Mr. McCormick received in return something more substantial than thanks. While there are many other and excellent reapers, the name of McCormick will stand as the pioneer of all, and occupies a proud position as one of the benefactors of agriculture.

Rev. E. P. Roe, the writer on small fruits and other topics, having decided to devote his entire attention to literature, pure and simple, has disposed of his Nurseries at Corn wall-on-the-Hudson, to Mr. H. G. Corney, long his confidant, and able first assistant.

Fountain Pumps.—Our nearest neighbor has some fine large cherry trees badly infested with aphides (plant lice), and we have recommended him to get a force pump, and spray the infested leaves and branches with a decoction of tobacco water. He needs the pump for washing the windows of his dwelling, watering the young garden vegetables and flower beds, and for many other purposes. The Fountain Pumps which are made by J. A. Whitman, Providence, R. I., have a world-wide reputation.

A "Farmer's Friend."—A strong, well-made, keen-edged knife, should be the delight of every farmer, as with it one has a ready means of temporarily mending a harness or implement while at work. The ability to shape a wooden pin has often saved a half day for team and man at a time, when any delay might have been disastrous. Let every farmer go armed with a first-class pocket knife kept in good order. Our old patrons, Maher & Grosh, Toledo, Ohio, furnish pocket knives of various kinds, that give satisfaction; their goods advertise the reliability of the makers and dealers.

FEARLESS.

VICTORIES

The only machine that received an award on both Horse-power and Thresher and Cleaner, at the Centennial Exhibition; was awarded the two last Gold Medals given by the New York State Agricultural Society on Horse-powers and Threshers; and is the only Thresher selected from the vast number built in the United States, for illustration and description in "Appleton's Encyclopedia of Applied Mechanics," recently published, thus adopting it as the standard machine of this country. Catalogue sent free. Address MINARD HARDER, Coldest III, Schenhar Co., N. Y.

UNEQUALLED

ARTIFICIAL LIMBS
MARKS' PATENTS.

With Rubber hands and feet. The most comfortable, durable, and useful. In practical use in all civilized nations. U. S. Government Manufacturer. Established 1858. Large illustrated pamphlet, in English or Spanish, sent free. Also, a SYSTEM of MEASUREMENT, by which limbs can be made and sent to all parts of the world with GUARANTEED SUCCESS.

THE OLD RELIABLE HALLADAY STANDARD WIND MILL

27 YEARS IN USE.

GUARANTEED

Superior to any other make.
17 Sizes-1 to 40 H. Power
Adopted by U.S. gov.
at forts and garrisons
and by all leading U.
R. Cos. of this and
other Countries.
Also, the

Celebrated I X L Feed Mill,

which can be run by any power and is cheap, effective, and durable. Will grind any kind of small grain into feed at the rate of 6 to 25 bushels per hour, according to quality and size of mill used. Send for Catalogue and Price-List. Address
U. S. WIND ENGINE & PUMP CO. BATAVIA ILL.

THE DANA CENTRIFUGAL-COVERNOR WINDMILL.

This is the best working, and the most powerful Wind-Engine in the world, because of—first, the superior excellence of its self-regulating mechanism, and second, the better form and position of its sails. The facts and reasons which support this claim are set forth in our Descriptive Catalogue, Second Edition—1884, for which apply to

The Dana Windmill Co.,
FAIRHAVEN, MASS., U. S. A.

Old Reliable Stover Improved.

We are the Sole Owners and Manufacturers of the Stover Pumping Windmills for pumping water for Railroads, Villages, Suburban houses, Lawns, Dairies, Brick Yards, Draining, Irrigating, etc., as well as Geared Windmills of all sizes, for running Grinders, Shellers, Saws, etc. Also Feed Grinders operated by Pumping Windmills. Corn and Cob Double-faced Grinders with Sweep, Corn Shellers, Wood Saws, Corn Cultivators, and implements generally.
FREEMONT MACHINE CO.,
FREEMONT, ILL., U. S. A.

7,000 Challenge Wind Mills.

IN USE IN EVERY State and Territory of the U.S. It is a section wheel, has been made by us for 15 years, and has never blown down without tower breaking, a record no other mill can show. **MILLS SENT ON 30 DAYS TEST TRIAL. BEST FEED MILLS, CORN SHELLERS, ETC. GOOD CATALOGUES FREE. CHALLENGE WIND MILL AND FEED MILL CO., Batavia, Kan. Co., Ill.**

HERCULES WIND ENGINE.

The principles of a Turbine applied to a Wind Motor. We desire to call attention to the following extracts from a private letter, illustrating the superiority of the Hercules.
"My ten-foot Hercules drives a 12-inch Burr mill, elevates all my grain, besides pumping all water for my stock. I was grinding corn to-day, the grinder making about 1,000 revolutions per minute, when a man came in, and after looking at the mill, asked if it was bolted it was ground so fine. It operates in a very light breeze. All who have seen it, pronounce it the finest thing they ever saw. It is placed inside the cupola of my barn. Yours very truly,
JAMES HOSFLANDER,
N. Ridgeville, Lorain Co., Ohio.

Some New and Practical Books.

"Superior Fishing," or the Striped Bass, Trout, Black Bass, and Blue-fish of the Northern States," by Robert Barnwell Roosevelt. Orange Judd Company, New York. This work is not, as one might infer from its title, devoted to fishing in Lake Superior. While a large share of it is occupied with an account of an excursion to that interesting region, it treats of the superior fishes above named wherever they may be found. It gives very full instructions for the making of artificial flies, and its hints upon camping are most useful even to those who are not altogether novices. There is a very important chapter on Cookery for Sportsmen, giving directions for the preparation of fish and game in the most approved camp style. The author has no doubt learned from experience, that there are times when the line and the gun fail to supply the camp larder, and he has sensibly guarded against these, by including in the outfit for the excursions, pork, beans, hard-tack, and other well known camp luxuries, and talks learnedly about cooking them. As an author, Mr. Roosevelt has something to say, and a most genial method of saying it. He describes the grandours of Lake Superior, and the incidents of the excursion in a clear, vivid manner, and gives directions for preparing "Fried Mush" in a style, that sets the reader's appetite on edge. The work is a model of its kind, with not a dull line in it. The graces of a most charming style so elevate a common-place subject like chowder, as to make it seem to be something worth living for. Many such works are tedious from the egotism of the writer, a fault of which Mr. Roosevelt can not be accused. A capital work to take upon a summer excursion; no matter where one goes to pitch his fishing camp, he will find it a helpful companion. Price, post-paid, \$2.00.

"Our Friend, the Dog," is the taking title of a most attractive book, by Gordon Stables, C. M., M. D., etc. Loudon, England. The sub-title informs us, that it is "A Complete Guide to the Points and Properties of all known Breeds, and to their Successful Management in Health and Disease." The author has one important qualification for his task—he is in love with his subject, and writes so earnestly as to inspire his reader with a similar love. He invests the most common-place matters with a peculiar charm, and while anecdote and poetry are brought in to embellish the pages, there is a solid substratum of fact, and such a vein of common sense pervading all he tells us about dogs, and how to manage them, that he inspires us with confidence in his teachings. The characters of the numerous breeds are sharply given, and besides the topics usually treated of in such works, he gives much needed information on points generally overlooked by authors who write about "Our Friend, the Dog." One of these of growing importance in this country, is useful hints about exhibiting at Dog Shows, and some excellent advice is given to the managers of Shows, which indicates that human nature is much the same on both sides of the Atlantic. A number of chapters are devoted to "Clubs." These are very full of just the information needed by those who would organize Dog and Kennel Clubs in this country. The Constitutions and Rules adopted by the leading Associations of England will be very useful. The work is abundantly illustrated by engravings, not only of dogs, but of the various kennels and other appliances. The leading breeds are illustrated to a great extent by portraits of noted representatives, a historical sketch being given of the animals in a chapter on illustrations.

The work will no doubt occupy a similar place in the literature of the subject that has been accorded to it in England. Published by Orange Judd Company, New York. Price, post-paid, \$3.00.

Practical Forestry, by Andrew S. Fuller. Orange Judd Company, New York. Some twenty years ago Mr. Fuller wrote a hand-book upon the various methods of propagating our native forest trees. It was intended to be a small pamphlet, giving the methods of propagation only. His then publishers induced him, against his better judgment, to extend the work in order that it might be issued as a bound volume, and it finally appeared as a work of one hundred and eighty-eight pages. While the work, one of the earliest upon forest tree culture, was the most useful, indeed the only one available, it was so incomplete, that the author was from the outset dissatisfied with it, and determined that whenever it should be practicable, to issue a work on forestry more in keeping with the importance of the subject. The obstacle to its publication having been removed, Mr. Fuller has not added to and enlarged his earlier book, but replaced it by an entirely new work, entitled "Practical Forestry." Especial attention has been given to the various methods of propagating forest trees. Indeed this is the most important matter relating to forest tree culture at present. Our

supply of timber and fuel is not to be increased by large plantations by companies, etc., but by individual effort. Upon nearly every farm, in the older States at least, there is more or less land suited to forest tree culture—and to nothing else. If every farmer owning such land could be induced to plant it with trees, a long step would be taken in the improvement of our supply of timber and fuel. But the average farmer, while he will admit the force of all the arguments in favor of planting trees, will rarely devote the few dollars needed to purchase the young stock to make a plantation, and nothing is done. If the farmer finds that he can, without any money outlay gather seeds or procure cuttings from which he can raise a stock of young trees for planting upon his otherwise useless land, he will then take a different view of tree culture. It is for this reason that we regard the propagation of trees a most important part of a work on forestry. Show farmers that they can raise trees for planting without money outlay, and they will be willing to undertake it. Mr. Fuller, from his wide experience in raising young trees of all kinds, is abundantly able to teach the readiest methods, and to point out whether, for a given kind, it may be most readily propagated from seeds, by cuttings, by grafts, or by other methods. All our useful native forest trees, and a few foreign ones are noticed in the work. A description, sufficient to allow one to identify the tree is given of each species, the methods by which it may be best propagated, its uses, etc., make this a most useful hand-book for the farmer, no matter in what part of our wonderfully diversified country his lot may be cast. In press. Price, post-paid, \$2.00.

The Shepherd's Manual, a Practical Treatise on the Sheep, Especially Designed for American Farmers, by Henry Stewart. Illustrated. A new Edition, revised, enlarged, and brought up to date by the Author. Orange Judd Company, New York. Mr. Stewart's "Shepherd's Manual" first appeared about eight years ago, and at once took its place as the leading work upon Sheep Husbandry. Unlike the American works which preceded it, it was not devoted to any particular breed, but to sheep. Nor was it addressed to the Sheep-growers of any one locality, but to those of the whole country. That a work with such a wide scope should meet with a correspondingly wide circulation, was hoped rather than expected. A new edition was called for at the end of two years, and that is now followed by the present edition. The principal new matter here added relates to the localities available for sheep ranges, and in this the most recent knowledge is presented. No book can supply the lack of common sense, but one with this essential outfit, can, by the aid of the teachings of the present work, undertake sheep-raising in any locality he may prefer with confidence of a successful result. One who contemplates a shepherd's life, should first decide which branch of the husbandry he will adopt. If he proposes to raise early lambs for market, he will select a very different locality from one who looks to the clip of wool as his source of profit. This work will both aid in the decision, and be a useful guide in the management of the flock. In the treatment of the various diseases to which sheep are liable, and in all other matters relating to the subject, the "Shepherd's Manual" is by far the most complete and useful book thus far offered to the American farmer. The keeping of a small flock of sheep as a part of a mixed husbandry, is properly becoming more frequent. As destroyers of weeds, and as improvers of the soil, their true value is being appreciated. Besides these, their use in supplying the farmer's table with excellent food, is an important reason for keeping them, and small flocks are becoming more common. Those who keep sheep on a small scale, or a large one, will find Mr. Stewart's work a useful guide. Price, post-paid, \$1.50.

A Practical Treatise on Ensilage and Silos.—This neat work of over a hundred pages, contains many letters giving the valuable experience of prominent stockraisers and farmers. It is compiled and published by E. W. Ross & Co., manufacturers of the Ross Ensilage and Fodder Cutters, Fulton, N. Y. Doubtless every farmer at all interested in the preservation of green fodder may find valuable hints and suggestions in this practical treatise. As no price is named, and for other reasons, we presume the work can be obtained for the asking.

Sedgwick Steel Wire Fence

Is the only general purpose Wire Fence in use, being a
Strong Net-Work Without Barbs. It will turn dogs, pigs,
sheep, and poultry, as well as the most vicious stock,
without injury to either fence or stock. It is just the fence
for farms, gardens, stock ranges and railroads, and very
neat for lawns, parks, school lots and cemeteries. Covered
with rust-proof paint (or galvanized) it will last a lifetime.
It is superior to Boards or Barbed Wire in every respect.
We ask for it a fair trial, knowing it will wear itself
into favor. The Sedgwick Gates, made of wrought-
iron pipe and steel wire, defy all competition in neatness,
strength and durability. We also make the best and
cheapest All Iron Automatic or Self-Opening Gate, also
Cheapest and Neatest All Iron Fence. Best Wire
Stretchers and Post Anglers. Also manufacture
Russell's excellent Wind Engines for
pumping water, or geared engines for grinding
and other light work. For prices and particulars ask
hardware dealers, or address, mentioning paper.
SEDGWICK BROS., Mfgs., Richmond Ind.

New, Revised, and Enlarged Edition.

THE SHEPHERD'S MANUAL.

A PRACTICAL TREATISE ON

THE SHEEP.

DESIGNED ESPECIALLY FOR AMER-
ICAN SHEPHERDS.

By HENRY STEWART.

In his Preface to the new edition, the author says:

There can be no doubt that sheep culture, and the wool-
producing industry, will still continue its present healthful
growth, and before the next decade comes around, we may
see these become adequate, not only to supply our home
demands, but to furnish material for profitable foreign ex-
port of wool, as well as mutton. A million farms—only a
bare fifth of the number in this country—upon which now
the bleat of the sheep is not heard, can each support a flock
with economy and profit. All that is requisite, is, that
farmers will see how little it costs to keep a flock, and how
profitably it may be kept upon fodder which, at present, for
the greater part, goes into the manure heap and serves only
in its least profitable purpose. The sheep's foot is truly
golden, because it takes such fodder and turns its most val-
uable portion into mutton and wool, and still leaves the re-
mainder greatly increased in effective usefulness, as a rich
maure for the improvement of the land.

A Profitable Investment!

Each \$5 doubled within 30 days, and loss rendered impossible.

A NEW CITY BEAUTIFULLY LOCATED.

Hindsdale City, adjoining beautiful Garden City—the "loveliest village of the plain"—and Creedmoor Rifle Range, N. Y. Several thousand building lots, surrounding Hindsdale depot, \$180 each, selling on monthly payments of \$5 per lot; four lots, \$10 per month. Prices advanced \$5 per lot monthly until present prices are at least doubled. Cottages \$10 monthly for each \$1,000 of cost. Nuisances and shanties prohibited; no malaria, chills, fevers or mosquitoes; climate, soil, drives and surroundings unsurpassed. Building optional with purchaser; fair dealing guaranteed; nothing over-colored. Buy for investment, residence or Summer home. New York will be

THE FUTURE CITY OF THE WORLD.

Property around it is rapidly increasing in value, and must continue to do so. You enter no uncertain venture by investing in Hindsdale. Prices are low compared with all other New York surroundings; increase certain; prospective value greater than any property equidistant. Hindsdale is 13 miles from New York—35 minutes by rail, and 5 minutes additional by Brooklyn Bridge or Ferry; and the commutation averages 10 cents per trip. It is on the main line of the Long Island Railroad, and is the junction for both Garden City and Creedmoor Rifle Range. Improvements proposed, etc., will render Hindsdale an attractive place of abode. Agents wanted of every sex. Circulars, etc., of

R. WILSON, Attorney, 335 Broadway, New York.

AMERICAN AGRICULTURIST, 751 Broadway, New York.

New Books for Sportsmen.

The Game Fish

OF THE

NORTHERN STATES AND BRITISH PROVINCES.

WITH AN ACCOUNT OF THE

Salmon and Sea Trout Fisheries of Canada and New Brunswick, together with Simple Directions for Tying Artificial Flies, etc., etc.

BY ROBERT BARNWELL ROOSEVELT.

CLOTH, 12mo. PRICE, POST-PAID, \$2.00.

NOTICES BY THE PRESS.

Mr. Roosevelt writes with a sportsman's enthusiasm and love of out-door life.—*Journal*, Boston.

Many who are going into the country for recreation will enjoy just such a book as this.—*Observer*, New York.

The world of sportsmen owe Mr. Roosevelt more than a passing tribute, and the generation of anglers in years to come, will bless his thoughtful providence.—*Graphic*, New York.

It contains, we should judge, a complete compendium of the knowledge needed by the votaries of the rod and line for success in their favorite sport.—*Bookseller and Stationer*, Chicago.

Mr. Roosevelt is an enthusiast with the rod, as well as gun, and he writes well on the subject of sport. There will be a lively demand for his book on fish.—*Turf, Field, and Farm*.

Mr. Roosevelt is an authority whom none dare question, and whatever he may say on his favorite subject, will be received with pleasure by all hearers of the rod and fly.—*The Globe*, Boston.

His work is of a practical nature, well illustrated, and the thorough student of it, if he caught no fish, would have the consolation of having deserved success, and could huy of those who were more fortunate.—*The Churchman*, New York.

The preparation of this work has been to Mr. Roosevelt a labor of love, and the reader who follows him in his faithful pictures of the finny tribe, and in his graphic descriptions of his encounters with the powerful and gamey denizens of the streams, will have a lively appreciation of the author's feelings, and share with him in his enthusiasm.—*Chicago Journal*.

Here we have the finny beauties of the brook, and river, and sea. The style of the work is attractive, and will interest the general reader almost equally with the amateur sportsman. The haunts and habits of the different fishes, their food, and the best way of securing them, are amply treated in this handsome and entertaining volume.—*Zion's Herald*, Boston.

Mr. Roosevelt is one of the very few American writers on angling, who understand their subject, and know how to express their knowledge and opinions clearly and interestingly. The book in question has had two previous editions, in 1862 and 1865. The present one, Mr. Roosevelt states in his preface, contains "a great deal of fresh matter," and the information and directions have been brought down to the present time.—*The Nation*, New York.

Though very few of us have as much time as Mr. Roosevelt on our hands, yet we can fully sympathize with him in his enthusiastic devotion to the healthful out-door life of the fisherman, and can read with a certain degree of interest, what he has to say on the salmon and sea-trout fishing of Canada and New Brunswick, on fish culture, or tying artificial flies, and on all those little points that belong to the experienced angler.—*Daily Advertiser*, Boston.

A great merit of Mr. Roosevelt's book is, that while it is instructive to the followers of the gentle art, it is most interesting to those who never tied a fly or cast a line. The style is free and familiar, but still elegant, and if we cannot enjoy the reality of a day with the author, by the waters of New Jersey, amid the beauties of the Thousand Islands, or in the breadth of the Saguenay, we can, at least, led by his vivid descriptions, follow him in idea, and participate vicariously in his sports.—*New York Times*.

FLORIDA,

AND THE

GAME WATER BIRDS

of the Atlantic Coast and the Lakes of the United States.

ILLUSTRATED.

With a full account of the sporting along our seashores and inland waters, and remarks on breech-loaders and hammerless guns.

BY ROBERT BARNWELL ROOSEVELT.

CLOTH, 12mo. PRICE, POST-PAID, \$2.00.

Every reader of the *American Agriculturist*, who wishes to know about Florida, or contemplates going there, should send for this entertaining volume.

NOTICES BY THE PRESS.

Of great interest to sportsmen.—*Gazette*, Boston.

The story of the cruise is fresh and fascinating, and the general reader as well as the sportsman will enjoy it.—*Chicago Evening Journal*.

Besides its abundance of facts, the book has a genial but natural air, with a fine taste of out-door life about it, which adds not a little to its value.—*The Times*, Phila.

Tells all that he knows about game water birds, and the most approved and successful methods of shooting them.—Bright and cheery reading.—*Mail and Express*, New York.

Sold at \$2, which is a low price for a duodecimo of 450 pages, unusually handsome and well made. It is a long time since any kind of a sporting book has appeared that seemed to possess so much real value.—*Cultivator and Country Gentleman*, Albany, N. Y.

A full account of the sporting along our shores and inland waters is given in such a captivating manner, that the reader almost imagines himself one of the happy party that made up the excursion.—*The Signal*, Babylon, L. I.

A hook of pleasant descriptions of sporting experiences, full of interest and instructiveness in their way, with many particulars in regard to birds of different sorts, their habits, and the way to shoot them.—*Congregationalist*, Boston.

Written in a familiar and attractive style, and will not only interest the "mighty hunters," but our many amateur sportsmen, who find in the gun and reel the best active recreation for the summer vacation.—*Zion's Herald*, Boston.

The contents of the volume fully justify its comprehensive title, while the Publishers, Orange Judd Company, have done their share of the work well, thus making the book attractive as well as instructive.—*The Spirit of the Times*, New York.

Characteristics and habits of game water-birds are given in detail. Game protection is discussed. Guns and rods are treated of at length, and the handling of these is described as carefully as the art ertie would exhibit the technique of a work of difficult execution.—*Boston Daily Advertiser*.

To the account of the Florida trip has been added a revision of a former book on the Game Water-birds of the Atlantic Coast and the Lakes, and those who have long sought in vain for a copy of the first edition, will welcome this reprint. In the several chapters Mr. Roosevelt has stored up a rich fund of gunner's wisdom, and we can heartily commend the work to the novice, who will find here more than he will probably ever learn by experience.—*Forest and Stream*.

The Florida excursion, of which Mr. Roosevelt gives a lively and interesting history, was undertaken with an eye to sport, and exhibits the practical application of a great deal of the technical knowledge set forth in part second. Mr. Roosevelt and a congenial party, including ladies, made a winter trip to Florida in a small yacht, or sharpie, drawing one or two feet of water, and spent a delightful season, hunting, fishing, and exploring in waters, of which the ordinary tourist knows nothing whatever. The descriptions are clear without prolixity, the sporting episodes show the same touch of an expert, the narrative is easy and vivacious, and the whole record is permeated which good humor.—*New York Tribune*.

Superior Fishing;

OR,

The Striped Bass, Trout, Black Bass, and Blue Fish of the Northern States.

Embracing full Directions for Dressing Artificial Flies with the Feathers of American Birds; an Account of a Sporting Visit to Lake Superior, Etc., Etc., Etc.

BY ROBERT BARNWELL ROOSEVELT,

ILLUSTRATED.

CLOTH, 12mo. PRICE, POST-PAID, \$2.00.

NOTICES BY THE PRESS.

"Superior Fishing" comes just in time to give suggestions for summer sport to all lovers of the hook and line....It is unnecessary to say that any work on this subject from the hand of Mr. Roosevelt is founded in the most thorough knowledge and appreciation of all that pertains to the sport.—*Commercial Advertiser*, New York.

The author gives the reader the results of his sporting visit to Lake Superior, Point Judith, and other places, where he plied his exceptional skill as an angler among the striped bass, trout, black bass, and blue fish, of those waters. A large portion of the book is taken up with directions for fly-making, and with useful points on fly-fishing, and on cookery for sportsmen. It is rare to find a sportsman so intensely enthusiastic in print as Mr. Roosevelt.—*Daily Advertiser*, Boston.

Mr. Roosevelt has fished in many waters, and he devotes himself here to Superior Fishing (meaning the fishing on Lake Superior), to which he has added the kindred excitement that one finds off Point Judith. What every good fisherman knows about striped bass, trout, black bass, and bluefish, he knows—and more too, as the Celtic saying is—and makes his readers know also, and they have but to follow his direction to become superior fishermen.—*Mail and Express*, New York.

OUR FRIEND, THE DOG.

August Days.

'Tis summer prime, when the noiseless air
In perfumed chalice lies,
And the bee goes by with a lazy hum,
Beneath the sleeping skies:
When the brook is low, and the ripples bright,
As down the stream they go,
The pebbles are dry on the upper side,
And dark and wet below.

MRS. E. OAKES SMITH.

The Harvest Moon.

Husbandmen in ancient times looked upon the "unusual behavior" of the Harvest Moon, as due to a Divine dispensation in their favor, for the purpose of affording them abundant light to enable them to complete the labors of the harvest. At other times the moon rises about forty-eight minutes later than it did on the previous night, but the harvest moon rises nearly at sunset, and at about the same time for several evenings in succession. The astronomers dispose of the belief of the ancient farmers, that it was a dispensation for their special benefit, by showing that so long as the motions of the earth and the moon are as at present, the latter cannot help rising in such a manner as to produce the harvest moon. The influence of the moon in various worldly affairs has been a matter of common belief from very early times, and there are still those who sow seeds, cut timber, kill pigs, etc., at a certain time of the moon. The rural population of England have several fancies regarding the harvest moon; among others, that it is the proper time for maidens to learn of their future through dreams. The harvest moon dreams should surely be favorable, as they require no little trouble in the way of preparation for them. The lass who would learn what the future has in store for her in the way of matrimony, must open a prayer book at the marriage service, and finding the words: "With this ring I thee wed," places upon them a ring, a key, a flower, and a sprig of willow; besides these, bread, cake, and other things, including cards, are laid in the book, which is wrapped in muslin and placed under the pillow. If she dreams of a ring, marriage will follow; if of willow, her lover will be treacherous, and there is a proper interpretation for whatever may be the subject of the dream. Should a goose be dreamed of, the unfortunate dreamer will marry more than once. Though the farmer in former times was grateful for the harvest moon, as it prolonged his working day, the farmer of to-day does not need her light for this purpose. Thanks to modern inventions, the days of the harvest are abundantly long for their lessened labors. Instead of taking a practical work-day view of the harvest moon, he can, with grateful heart for abundant crops, give himself up to a full enjoyment of the scene, when

"A dewy freshness fills the silent air;
No mist obscures, nor cloud, nor speck, nor stain,
Breaks the serene of heaven:
In full orb'd glory, yonder moon divine
Rolls through the dark-blue depths."

We now make to Agents and Canvassers the same request previously made to subscribers, viz.: that they immediately forward us any autograph letters, any documents with the ear-marks—or any printed matter whatsoever, received by them, indicating that there may have been an organized conspiracy to dishonorably or dishonestly appropriate the subscription list and good-will of this Company.

Make repairs..
Carry a note book.
Watch the markets.
Favor the seed-corn hills.
Manure the back fields!
Keep up the flow of milk.
Make repairs in spare hours.
Superior work pays us the best.
Above all things avoid foul seed.
Gas lime should not be used fresh..
Idle land is the weeds' opportunity.
Fowls profit by a run in the stubble.
Wheat after oats is a faulty practice.
Whitewash will cleanse and sweeten.
August pigs make holiday small pork.
Do not let your insurance policy expire.
The damages by rats exceed those by fire.
Sow white turnip seed for fine fall fodder.
Wash the horses feet and legs every night.
Success is largely a matter of small details.
Roll the ground before and not after seeding.
Good seed and good soil are a good beginning.
Farm animals well summered are half wintered.
Help out the dried up pastures with green fodder.

Thinning the root crops means more tons to the acre.

Clean oil, and store all the implements no longer in use.

Get out the year's supply of muck while the beds are dry.

Build temporary pasture shelter in airy parts of the fields..

Weeds when they go to seed curse the land that grew them.

The general purpose animal is superior only in its versatility.

Let the bumble bees live and thus increase the yield of clover seed.

A drain to be a profitable investment must be a permanent improvement.

Fall following cleans the land and brings it into fine condition for spring crops.

Neglected fence rows are like a leaden weight upon the neck of clean field culture.

A farmer's bank account may grow at the expense of his manure heap and grain crops.

A clean, cool, ventilated stable, free from flies, is a suitable lodging for the tired work horse.

The possibilities of a farm are measured by the quantity and quality of brains which run it.

Amid all the toil of midsummer, do not forget to do a little careful work for the coming county fair.

Superior pork made from freshly fallen wormy apples is very cleansing to an insect-infested orchard.

A root crop is very humble, but as a foundation for a judicious rotation it will support the symmetrical superstructure of profitable mixed farming.

Orchard and Fruit Garden.

Decide whether to dispose of surplus and inferior fruit, by making it into vinegar, or by drying or evaporating it....Trees will be broken by careless pickers; saw off all injured limbs....The Apple-worm may be diminished by picking up and destroying fallen fruit, or allowing the pigs to do it....Bands of carpet, bagging, or other fabric, fastened around the trunks of apple trees with a single long tack, will catch many Apple-worms. Examine weekly and kill....If trees set last spring suffer from drouth, mulch them, or keep the soil loose....The Fall Web-worm spins its nest in summer also. At its first appearance, cut away the twig to which the nest is attached, and crush the worms....Young trees may have their shape controlled by pinching the ends of shoots that grow too vigorously....When the Blackberry and Raspberry crops are off, cut away the canes that have borne fruit. The new stems of Blackberries should be stopped when five feet high, those of Raspberries at three or four feet....Keep strawberry beds free of weeds. Plant new beds with plants rooted in pots....Whitish spots on the underside of grape leaves are mildew. Dust sulphur, with a sulphur-bellows at once. Large caterpillars and beetles must be hand-picked. Continue to pinch laterals.

Market and Kitchen Garden.

The hotter and drier the weather, the faster the "pussley" grows. Hoe up and feed it to the pigs....Vegetables for market should be put up neatly. Beets and other roots must be washed and tied in bunches....Plant Bush-beans for late crops. Pinch off the ends of the vines of Limas when they reach the tops of the poles....Beets, carrots, and other roots should be hoed until the tops prevent....The fodder from sweet-corn may be greatly increased by cutting up the stalks as soon as the ears are gathered. Cultivate well....Gather Cucumbers for pickles as soon as they are of the desired size....Keep the fruit of Egg-plants from the ground with a wisp of straw or hay....As Melons approach maturity, turn to secure even ripening....Do not allow Sweet-potato vines to take root at the joints; move them at each hoeing....Onions are known to be ripe when a large share of the tops fall over. Pull, dry thoroughly, cut off the tops, and sell, or store in a dry, cool place, spreading thinly....Cultivate and hoe among the Squashes as long as the vines will allow. Permit the vines to take root at the joints....Late Cabbages and Cauliflowers need to be kept free from weeds....Turnips are to be sown; the ground from which the early potatoes were removed is excellent for them. Sow Rutabagas early this month, and the Aberdeen and Yellow Stone any time before September first....Tomatoes, foliage, stems, and fruit are devoured by a large green worm or caterpillar, which can neither bite nor sting, despite its horu. Wherever its abundant droppings are seen on the ground, hunt on the vine for the worm. Keep the vines tied up to the trellis, and cut away all badly shaped fruit.

Flower Garden and Lawn.

Do not mow the lawn too often in hot and dry weather. Keep the margins of beds, cut in lawns, well defined. Run a sharp spade into the soil, along the margins of the beds, to cut off grass roots....Ribbon or other beds planted in designs, need care to keep the lines between the kinds of plants distinct, and all at a uniform height; this may be done by pinching and the use of the knife....Sticks and strings will be needed by Dahlias, Gladioli, and other tall plants. Keep the supports out of sight....Remove flowers and flower-clusters as soon as they begin to fade, unless seeds are to be saved....As soon as flowers on the summer-blooming roses fall, cut back the shoot to a strong bud....Chrysanthemums should be brought into shape by pinching. When buds are formed, pot those intended for house-blooming. Look out for caterpillars and plant-lice....Lilies, especially the tall growers, may need stakes. If thin spots appear on the leaves, a caterpillar will be found on the under side. If seeds are not wanted, cut away

the young pods....Carnations, to bloom in winter, should have flower stems cut away as they appear.

Greenhouse and Window Plants.

Paint, glaze, and repair the greenhouses....Secure pots, soil, sand, moss, and whatever else may be needed for winter use....Care for the plants in pots out of doors as directed in former months....Make cuttings of plants that were turned into the open ground....Camellias and other plants with thick leaves must not be exposed to the full sun. Fumigate house plants with tobacco smoke.

A New Celery.—The "White Plume."

No other agencies have done so much to popularize celery culture and make it profitable, as this periodical. Some twenty years ago, in the pages of the *American Agriculturist*, and soon after in our volume, "Gardening for Profit," by Peter Henderson, were first made known the improved methods of raising celery and keeping it, practised by the gardeners who supply the markets of New York City. The publication of these methods completely revolutionized, and gave a new impetus to, celery culture throughout the country. Only a few gardeners, who left the old country too late in life to learn new ways, continued to follow the former method of planting in trenches. Not only were these new methods of treating the crop of great service to growers of celery, but an almost equal

THE "WHITE PLUME" CELERY.

benefit resulted from the advocacy of the dwarf varieties, which grow to the height of about two feet or less, in place of the tall kinds reaching the height of three feet or more. The tall kinds require the growing of a foot or more of useless leaves, involving extra labor in their culture and in storing the plants. The dwarf varieties afforded as much of eatable stalk as the tall kinds, while they could be produced at much less cost. A few years ago, a New York grower of celery, noticed in a bed of seedlings of one of the dwarf varieties, a single plant, that in the shape of its foliage and in its habit of growth, was very different from all the other plants in the bed. This singular plant was carefully preserved, and was found to perpetuate its peculiarities by seed, and thus became the parent of a distinct new variety, which has been named the "White Plume." The name was suggested by the form of the inner leaves, which being greatly sub-divided and feather-like, form a beautiful ornament for the table. But this is not the most marked peculiarity of the "White Plume." The broad outer leaf-stalks grow in such an upright and compact manner, that the inner stalks are so compressed and deprived of light, that the plant becomes self-blanching. This peculiarity of the plant greatly lessens the labor required by the celery crop. In the beginning the "White Plume" requires the attention that must be given to all

other kinds of celery; i. e., the plants must be raised and transplanted to the rows where they are to grow. With ordinary kinds of celery, after the plants have nearly made their growth, they are "handled," that is, the leaves are brought into an upright position, and kept there by pressing the soil firmly against the base of the leaves with the hands. After this, to blanch the celery, the earth must be banked upon each side of the row, to exclude the light. With the "White Plume," the labor stops with the "handling," the peculiar growth of the plant completing the blanching, as shown in the engraving. The "White Plume" promises to still more simplify celery culture. Its history is especially interesting, as showing the importance of noticing any marked variations among cultivated plants, and if these promise to be of value, of caring for and propagating them.

Getting Ready to Sow Winter Wheat.

JOSEPH HARRIS.

If winter wheat is to be sown after early oats, peas, beans, early potatoes, or corn-fodder, the moment the crop is off the ground, stick in the plow, or gang, or cultivator. Do not wait for rain. The weeds and stubble will pump up more water from the soil than any ordinary rainfall at this season will be likely to furnish. If you plow, or in anywise work the land, it will not only destroy the weeds and check the rapid evaporation of water, but should we have a shower, the rain will penetrate deeper into the worked soil, and render it soft and mellow. We have everything to gain and nothing to lose by promptness in plowing immediately after the previous crop has been harvested.

In four years out of five, the principal difficulty in sowing winter wheat in proper season is to get the soil moist enough to cause the wheat to germinate vigorously and evenly. We must recollect that the soil, even during a severe drouth, contains in the first two or three feet a great many thousand gallons of water per acre, and still more at a greater depth. This water is constantly rising towards the surface. Any growing plant pumps it up out of the soil, and evaporates it into the atmosphere. The amount of water thus evaporated is enormous. The bare soil evaporates water from the surface as long as there is any to evaporate, but the loss of water from a bare soil is nothing in comparison with the loss on land upon which plants are growing.

In the winter wheat section of Western New York we sow our wheat from the 1st to the 20th of September. It is ready to cut from the first week in July to the first of August, varying greatly in this respect according to the season. As we go South, wheat is sown later in the autumn, and is ready to harvest earlier in the summer.

Where the Hessian fly is troublesome, we have to avoid early sowing in the autumn. The fly lays its eggs in the young wheat plants in the autumn, and late sowing is one of the remedies. On the other hand, when wheat is liable to injury from the Midge, we have to avoid late sowing. The Midge flies lay their eggs in the ears of wheat when it is in blossom, and an early crop of wheat is far less liable to injury than a late crop.

Fortunately neither the Hessian fly nor the Midge has done much damage of late years, and the tendency among our best wheat-growers is towards earlier sowing. After the first of September it is thought desirable to sow as soon as the soil can be got sufficiently moist and mellow. It is just here where promptness, good judgment and science are all requisite. Rain will help us, but it will help us still more if we go to work as though no rain was expected. As we said before, there is water enough in the soil, but it is not near enough the surface to cause the seed to germinate. What we have to do is to hurry all the weeds, stubble, and growing plants, and keep the surface soil fine by the frequent use of the cultivator, harrow, and roller. We know this is easier said than done—but on our strong wheat land it is the general experience, that much of our success will depend on our ability to get the wheat well started in the early autumn.

Bee Notes for August.

W. Z. HUTCHINSON.

HOW TO MANAGE ROBBER BEES.—At the close of a honey-flow, and especially the bass-wood honey harvest, bees are inclined to rob. Let a hive be open five minutes at such a time, and a horde of hungry robbers are ready to pounce upon any exposed portions of the combs. A part of the honey crop is usually upon the hives at the close of the harvest, and the task of removing it is attended with "unpleasantness," and sometimes with loss. The queen breeder must necessarily open hives and handle combs, whether robbers trouble or not. When examining the bees in preparing them for winter, robbers are often particularly troublesome. To save themselves from these annoyances, many bee-keepers have a small tent, in which they can perform the work of the apiary. This consists of a light frame-work covered with mosquito netting, easily carried from place to place, and set over the hives that are to be opened. The simplest and most convenient style of bee-tent known to the writer is shown in the illustration given below.

The strips *a, b, c, and d*, are straight-grained pine, eight feet long, one inch thick, and an inch and one-fourth wide. They are held together where they cross by ordinary wood-screws. Their upper ends are tied together with stout twine, that passes through small holes. The "ridge pole" is a piece of heavy tarred twine. An inch from the bottom of each strip an ordinary wood-screw is

A BEE-TENT.

driven in until its head projects about half an inch. Upon each screw is placed a small iron ring, and to these rings are attached the cords of tarred twine, *f, g, h, i, j, k, l, and m*, which complete the frame-work of the tent. The upper ends of the wooden pieces are covered with sheep skin, to prevent them from punching holes in the mosquito bar covering. To keep the wind from upsetting the tent, the lower ends of the wooden strips are furnished with curved points of heavy wire, two or three inches long, that can be thrust into the ground. When the tent is in position, the bee-keeper raises one side, crawls under, and performs his task unmolested by the buzzing crowd outside. By slipping the iron rings, to which the cords are attached, off the screws, the wooden bars can be shut up like a pair of shears, thereby folding the whole bee-tent as easily as an umbrella.

GRADING, CRATING, AND SHIPPING HONEY.—The first grade should consist of only perfect, white combs, and it is the writer's opinion that, in many instances, there should be only this one grade of comb-honey. Some bee-keepers make a second grade of unfinished sections, but if the apiary is rightly managed, there will be but few of these at the close of the season, and it is better to extract the honey from them, and keep the combs until another season. Honey that is too dark for the first grade, should not, as a general thing, be stored in sections, as it is usually more profitable to extract it. Before crating, sections should be scraped clean of propolis. A small crate is preferable; it

is more easily handled, and less liable to be "dumped," while it sometimes enables the retailer to sell a whole crate of honey at once. Sections should be placed only one tier high in shipping crates; because if any combs of the upper tier become injured, the honey drips down and soils those of the lower tier. Some bee-keepers make a shallow "dish" of heavy manilla paper, and place it in the bottom of the crate, then if combs are injured the "dish" catches the honey, and prevents the soiling of other crates. All honey crates should have glass on at least one of their sides.

Small lots of honey should be sent by express, and large ones by freight. Express matter is necessarily handled rapidly, and when there is a large lot of honey to unload, it is apt to be jerked off in a hurry. When a large lot of honey is sent by freight, the consignee should be notified in advance, so that he may see to the unloading. Small crates should not be stacked up in a tall, upright pile, in a car, but built up in the shape of a low pyramid. If access can be had to one end of the car, place the honey there, as it will be protected on three sides from tumbling down, and upon the other it can be built up like a flight of stairs, which will pretty effectually prevent any crate from receiving a tumble. Always handle honey with care.

A New Process of Extracting Sugar from Sorghum.

In the extraction of sugar from the Sugar Beet, a great improvement was made some years ago in Europe. Instead of pressing the juice from the beets, the roots, finely sliced, were treated with water, which dissolved out the sugar and greatly simplified the process. The introduction of new varieties of Sorghum from which sugar can be procured, has given a new impetus to Sorghum culture, which is to be supplemented by new methods of treating the cane and extracting the sugar it contains. In the usual method, the Sorghum canes are passed through mills, having several erect or horizontal rollers, which express the juice. This milling is found to leave about forty per cent of the sugar which the cane contains, in the bagasse, or refuse cane, and is a dead loss. The chemist of the Department of Agriculture at Washington, D. C., reports his experiments with Sorghum, with a view of obtaining a more complete extraction of its sugar by means of diffusion. These experiments and their results are published by the Department in the form of a Bulletin, which those interested in the manufacture of Sorghum will do well to procure and study. As a matter of general interest to farmers, we give a mere outline of the methods. The first point was to reduce the cane to thin slices. For this purpose a machine was constructed, to which the ends of the cane were presented and cut into slices one-eighth to three-sixteenths of an inch in thickness. The sliced cane was then subjected to the action of water, in a "diffusion battery," consisting of eleven cells, each holding ten gallons. This battery is illustrated in the Bulletin, by an indistinct photograph, in which pipes of various kinds are in such numbers

Fig. 1.—A DIFFUSION BATTERY.

as to confuse. Each cell, apparently of cast iron, is thirty inches long by twelve inches in diameter. It has an opening at the top for filling, and another at the bottom for discharging. By a complicated system of pipes and cocks, water, hot or cold, is let into the top or bottom of each cell. We give in figure 1, three of the cells of the diffusion battery, simplified as a diagram, merely to show the working. In the diagram the pipe is so placed as to have the liquid from near the bottom of one cell pass into the top of the next, and so

on. The pressure of the city water was employed. The water in the first cell, *a*, being charged with sugar, is forced out from near the bottom of that cell into the second cell, *b*, which it enters near the top, and so on, throughout the whole battery of eleven cells, and that from the last cell is evaporated. The experiments showed, that cane con-

Fig. 2.—THE KEGS ARRANGED.

taining eighty-nine per cent of juice, yielded to the diffusion process about eighty-five per cent. The diffusion process will properly receive the attention of those who now extract sugar from Sorghum by the wasteful process of milling. Those who would experiment with diffusion, without going to the expense of constructing a battery like that of the Department of Agriculture, can construct a simpler apparatus by the use of small kegs. Each keg should have an opening at the top for charging, and one near the bottom for removing the spent Sorghum chips. By arranging the kegs at proper heights, as in figure 2, the liquid from *a* can be made to flow into the next, *b*, without the use of hydraulic pressure. The diffusion treatment of Sorghum promises excellent results, and whoever aids in adapting the method to small operators, will be a benefactor to the farming community.

Melons for Market.

There are, in the writer's neighborhood, a number of small farmers, to whom the melon crop is one of importance. When they are asked what variety of melons they raise, the answer usually is, "my own." These farmers have learned, by experience, that it is of no use to grow more than one kind of melon if they would keep the variety pure, and moreover, that by care in selecting the seed-bearing melons, each secures a form or strain so well suited to his soil, etc., that he is justified in calling it "my own." This appears to be the true course for those who grow melons for market, viz., when they once get a good variety to stick to it, and to improve it by great care in selecting the seed for future planting. Experience shows that melons of the same variety, while they may be alike in external appearance, often differ greatly in quality. Whether this may be due to crossing in the flower of the melon that bore the seed, or to the natural tendency of cultivated plants to vary, it is sufficiently frequent to establish this rule, viz.: Taste all melons before saving their seeds for planting, and reject the seeds of those that do not come up to the standard. It is only by this course that the quality can be preserved. But the growers above referred to, are noted for the large size of their melons, and as sending to the city the largest good melons that are offered. This size, as well as the quality, is the result of several years of careful selection of the largest, as well as the best, as seed-bearers. Not only has size been considered, but relative weight, as indicating thickness of flesh. Shape has also been regarded, and the melons are surprisingly uniform in this respect. What these melon-growers have done, that is, established for the neighborhood a market reputation for their melons, due to size, solidity and high excellence, can be done elsewhere, by following the same methods. Now, with the ripening of the present crop, is the time to begin a rigorous careful selection for next year's seeding.

Guernsey Cattle.

Some of our readers may not know that Channel Island cattle, which used always to be called Alderney cattle, are really of two distinct breeds. Those native to the Island of Jersey, are called Jerseys, and the rest are Guernseys—even those of the Island of Alderney. The latter island never has produced any number of fine cattle, and its name unfortunately was given to the Channel Island cattle by a mere accident. At one time England was making a great fortified harbor. Hundreds of vessels were going and coming to and from Alderney, and because they could get no return loads from that rocky little island, they went to the larger ones of the group, and whatever they brought, potatoes, butter, cabbages, cauliflowers (for which the islands are famous), or cattle, all were supposed to come from Alderney. This led to the application of the name, Alderney, to all the Channel Island cattle. The name remains, and is a good one to apply to any Jersey or Guernsey cattle which for lack of pedigree cannot be registered in the Jersey herd-book or are of mixed blood.

These cattle, the Guernseys, not less than the Jerseys, have proved themselves hardy, prolific, adapted to all countries, and admirable as family cows, and producers of the choicest butter. The Guernsey cow has not as yet figured so notably in the fashionable circles as has her cousin of the adjacent island. She is not credited with the same sylph-like delicacy of figure, or gazelle-like style. Her merits are of a more homely and useful order. She is heavier, and while a great milk and butter producer, has the quality of converting feed either into milk and butter, or into admirable beef, as the occasion may require. Her butter is much higher colored than the average of Jersey cows. So intense, indeed, is the color, that the presence of one Guernsey in a herd of six or eight common cows, or of eight or ten Jerseys, will give an agreeable tint to the butter all winter, provided there is proper variety in the feed supplied to her. The quantity of butter she is able to produce, is as yet undetermined. Some cows within our knowledge, have approached three pounds a day. Many are worthy of being in the "fourteen-pound list," if any such list has been, or is to be made.

Jersey breeders from perhaps the earliest periods have enriched their strains of breeding by the occasional introduction of Guernsey blood. In fact, it is a conceded point that the variable richness of color possessed by the Jerseys is largely due to a remote Guernsey cross. The variability in color,

ample in point, we refer to the well-known cow Jersey Belle of Seitate, now dead. She was completely of the Guernsey build and color, with perhaps slight shadings, which indicated Jersey blood. Her head and legs were delicate for a Guernsey, but not unlike many, and her butter, at least her grass-made butter, was yellow enough for a Guernsey. The cross of Guernsey and Jersey cattle will at any time produce just such cows in

tions a characteristic, or else they are extraordinary sports of nature. If the qualities are inherited, as without doubt they are, they will be transmitted to the progeny of such cows.

The breeder of Guernseys must therefore bear in mind that pedigree is the foundation of success. This pedigree must be written in butter. A few weeks ago, a famous Jersey bull was sold at auction in this city, in the very high prime of his life

THE GUERNSEY BULL "LANCER."—Drawn (by Forbes) and Engraved for the American Agriculturist.

style and general form, while in the matter of yield of both milk and butter, we have no doubt that among a lot of such cross-breeds, some would approximate even her extraordinary record.

The proper development of this excellent, beautiful, and useful breed, and the responsibility of making it popular, rests with the breeders of the American Guernsey Cattle Club. They cannot expect the breed to "boom" itself. No doubt there are families of extraordinary butter power—those ought to be found out and brought out. A few years ago it was enough for the lover of Jerseys to know that an animal he thought of buying was recorded in the Register of the American Jersey Cattle Club. Now, though that registration is essential, it counts for very little in determining the value of

a sure getter, of magnificent form and size, of the most fashionable color, the most illustrious animal of his breed in the world as a prize winner, and of an illustrious ancestry as prize winners, not however particularly famous as butter producers. Three years ago he sold for thirty-two hundred dollars. The breeders of the Island of Jersey felt his loss to the island so keenly that they sent over to buy him, but were outbid by an enterprising New York breeder. This year he sold for the low price of one hundred and forty dollars, simply because so few of his daughters, which have come to milk, prove of particular excellence as butter yielders, although they are one and all hard to beat in the prize ring. Butter is therefore the first consideration, both in the pedigree and in the individual if a female, and in his dam if a male, but above all in his daughters after he has come to maturity. A bull at three years old should have daughters in milk, the producing power of which can be tested. A two-year-old heifer, giving twenty to twenty-eight pounds of milk a day, yielding ten to twelve pounds of butter a week, is good enough. Such are exceptional, but they sometimes occur.

Next to butter comes form. In milk cows of great capacity, we find a characteristic form prevails. This is not an indication of much butter, at least not an infallible indication, for many great milkers are only moderate, and occasionally small butter producers. Still it is a good thing in a cow to be well formed for a milk yielder. This form has been cultivated, that is bred for, for years in Guernsey, and the best Guernsey cows now possess it. It is marked by a long body, much larger in the hind than in the fore-quarters, open ribs, a long, broad loin, wide, high hips, flat thighs, a deep flank, and a great expansible udder, with strong, tortuous milk-veins upon the belly and beneath the vulva. The favorite color for Guernseys is yellow-fawn with buff nose, yellow horns and hoofs. White spots are not objected to, and a white triangle in the forehead, and white switch are regarded as characteristic. Well-grown Guernseys are one to two hundred pounds heavier than average Jerseys, and the larger ones often approach the size of Shorthorns. Guernsey steers, or oxen, have occasionally been fattened to reach the weight of sixteen hundred to two thousand, or even two thousand two hundred pounds. Guernsey and half-

GUERNSEY COW "VESTAL OF LARCHMOUNT."—Drawn (by Forbes) and Engraved for the American Agriculturist.

ing, both in the skin and in the milk of Jerseys, plainly indicates a characteristic not thoroughly fixed in the breed. This color or "richness," as it is termed on the Islands, when highly developed in the more fashionable race, is so often associated with a rich, yellow-fawn, or yellow-fawn and white, or a positively light-red or red and white coat in Jerseys, that it offers another evidence that both are effects of the Guernsey cross. As a notable ex-

a cow supposed to be worth more than a hundred dollars. The butter record of her ancestry, and of cows known to be of her immediate kindred, determines her market value to be two, four, or six hundred, or even many thousands of dollars. The same must be, and we predict it soon will be, the case with the Guernseys. The great yielders, like "Elegante," for instance, draw their blood from sources in which butter has been for genera-

Guernsey calves are usually large, so that the use of Guernsey bulls is favored by farmers, who make veal of many of their calves. In these particulars the Guernsey is a strong contrast to the Jersey.

We present our readers on the preceding page, engravings of two excellent Guernsey animals. They are the property of Mr. H. de B. Schenck, of Larehmount, Lenox, Mass. The cow, "Vestal of Larehmount," (1507), (Guernsey Herd-book, number 686), is lemon-fawn and white, was dropped Nov. 1877, selected on the Island, and imported by Mr. Schenck. She is now giving eighteen quarts of milk a day. "Vestal" comes of a line of famous prize winners, and herself won third prize in a class numbering one hundred and four entries, at the Shows of the Royal Guernsey Agricultural Society, May, 1883. She was imported in September, calved April 16th, and two weeks after that date, one day's milk made two pounds six ounces of butter.

The bull, "Lancer," (131), was imported in dam, and dropped in August, 1878. He is fawn and white, of superior form and size. He won first prize at the Central Berkshire Stock Show at Lee, Mass., in 1882, and the next year first at the Berkshire, Mass., Agricultural Society Show at Great Barrington.

Egg-Eating Hens.

The very worst habit hens can get into is that of eating their eggs. Dropping eggs from the roosts, or about the houses and yards, and eating each other's feathers, are of little moment compared to

AN EGG TRAP.

it. It is a habit they learn from one another. If only one or two, or a few hens in a flock eat eggs, make short work with them. They will probably be found healthy and fat, and will at least make good broth, even if too old to roast. But if, as with a subscriber living at Grandin, Dakota Ter., who has one hundred and twenty laying hens, and gets only fifteen eggs a day, the case is different. It will probably pay to outwit the hens, and thus cure them. There have been many nests in use, for allowing the egg to roll out of the hen's sight as soon as laid. The engraving represents a section of a range of eight to twelve laying boxes, or nests, with each nest about a foot square, and separated more or less completely from the adjoining ones by a board partition. The bottom of all the nests is made by two boards, one of which is five inches wide, the other about eight. They are fastened so as to leave an inch-and-a-half space between them. Before they are nailed in place, some fine soft hay, *h*, is fastened upon the upper sides by tacking on strips of tape, leather, or list. Care should be taken to have this hay or grass lie smoothly, and that upon the narrow board must have only a few of its thin, soft ends hanging over the edge. The centre of each nest must be made out the broader board, and a painted wooden egg fastened on by a screw going through the board. When the hen enters such a nest, she will mistrust nothing; she will not eat the wooden egg, and when she lays her own it will fall through the bottom. The egg is received upon a mass of hay, or, much better, a piece of sacking, *a*, *b*, tacked to the underside of the narrow board, and at a lower point to the top of a board behind the box hinged

at the bottom. The sacking must be slack enough to allow the hinged board to open far enough to take the eggs out, but not so that they will roll out. There is an alighting shelf, *s*, and a broad cover over all, which may be hinged in the centre if desired, for the greater convenience of examining the nest. Such a range of nests, covered as described, may have a roosting pole a foot above it, and the droppings being caught on the top, can be readily carried off from week to week.

How and When to Shoe Horses.

PROF. D. D. SLADE, HARVARD COLLEGE.

Horse-shoeing has given rise to much controversy, yet it is a matter which in itself, so far at least as regards the principal object in view, is extremely simple and easily understood. The object of the shoe is the protection of the ground surface of the outer wall of the hoof against excessive wear. In the wild horse, the balance between the growth and the wear of the horn of the hoof, is equally maintained, but when civilization subjects the animal to hard and rapid labor upon paved and macadamized roads, then this balance is destroyed—the wear exceeds the growth. Hence the aim of the farrier is to ward against this condition of things by attaching a rim of iron or steel to the circumference of the foot. The moment this is done, however, the balance is again destroyed the growth will exceed the wear, necessitating in time the removal of this metallic rim, and the rednetion of the horn by artificial means. Although the growth of the horn downward is equal over the entire surface of the wall, it will usually be found that in the healthy foot, more must be removed from the toe than from the heels or quarters. This is because the shoe is firmly fastened at the toe, whereas, in the other regions, especially at the heels, there is a certain amount of motion allowed by the absence of nails, and consequently more or less wear takes place. This may be readily seen on examination of a shoe that has been worn for three or more weeks, the burnished line on the foot surface of the shoe showing distinctly the outline of contact. It may be asked whether it is not practicable in many cases to dispense with shoeing. We answer most unhesitatingly yes, with great benefit to the animal as well as to the owner. There are many country districts where the roads are of turf, or are sandy, and where shoes are unnecessary. If the colt is never subjected to this process, the foot acquires that natural firmness and hardness which will serve the animal under ordinary circumstances. In winter, when the roads are very slippery, and the horse is called upon for heavy draft, in many cases we must provide means by which he can gain a firmer foothold; and this, in the present state of our knowledge, can only be done by shoes furnished with calks. We do but follow a blind and foolish custom where we apply shoes without the necessity. When shoes have been constantly worn, and it is desirable to dispense with them, great care must be exercised in gradually accustoming the foot to this new condition, and no long or severe labor should be at once demanded of the animal.

Calks are detrimental under any circumstances, and should always be avoided if possible. There can be no reason or excuse for their use on road horses of light draft in summer, even on pavements. When actually required, it is very essential that they should have an equal bearing on all sides, at the toe as well as at the heels. Any unequal distribution of the weight of the animal is sure to bring about strains of the ligaments, sinews, and muscles. The fashionable heel of the modern belle is not more sure to lay the foundation for future suffering. No shoe should be allowed to remain upon the foot more than four or five weeks. Many farmers patronize the farrier who nails on the shoes so that they will remain more than double this time, with the idea that such a proceeding is economical, whereas, it is the furthest possible remove from economy. As the growth of the horn is constantly downward and outward, the shoe, which when applied weeks before, was fitted to the foot, has now become altogether too small, and

consequently there is constant pressure upon the sensitive portions at the quarters, causing corns and other affections. On the removal of the shoe, if again to be applied, the ground surface of the wall of the hoof must be reduced by the rasp to a perfect level, which can be attained by the eye accustomed to good work. The level of the untouched sole forms a ready and practical guide for the amount of reduction. Neither the sole nor the frog should undergo the least mutilation, since nature removes by constant exfoliation all superfluous horn, neither should the natural barrier at the heels, provided for the express purpose of keeping the foot expanded, ever be cut into, as is the almost universal custom, under the insane idea that it "opens out" the foot. No greater folly or barbarity can be committed, and no surer way could be devised for producing contraction with its attendant evils. The walls of the hoof should never be rasped. It is by this process that the external fibres of the horn are destroyed, the beautiful polish removed, and the internal surface exposed, whereby the entire structure is rendered more brittle and unfitted to perform its functions. Let the intelligent farmer who has hitherto given little or no thought to this important subject, follow the above instructions, and satisfy himself of their correctness, and tell them to his neighbors.

An Enemy to Maple Trees.

Among the many kinds of Bark-lice (*Coccidae*), is one which attacks the Maples. This was first described in 1868 as *Lecanium acericola*, along with another new species peculiar to the Osage Orange (*L. Maclurei*). Both these insects are shown in the engraving, that at the left being the one which attacks the Maple. The insects, on being hatched, attach themselves to the tender bark of the young shoots, and also to the leaves of the Maple. A scale is formed upon the back of the louse, seen in the dark portions in the engraving. From beneath the scale protrudes a snow-white mass of fine cottony threads, which cover and protect the eggs, and perhaps the newly hatched insects. The eggs are hatched in July. The description referred to is very meagre, and nothing is said of the means

MAPLE AND OSAGE ORANGE SCALE INSECTS.

for destroying the insect. Specimens were recently sent us by Mr. Chas. E. Keller, Shelby Co., Ill.

The insect was first discovered in Indiana and afterwards in Iowa. In the absence of any report as to the best means of destroying the insect, we should be disposed to try the Emulsion of Kerosene, described in March last, page 114. This should be freely thrown into the tree, using a garden syringe. This or any other application would be most effective, if it could be applied when the insects are first hatched, and before they have formed a scale, a point which can only be ascertained by close observation. Let us hear from any who have successfully treated this pest. Mr. K. states that the insect "is devastating the shade trees, and is beginning on the fruit trees."

A Good Strawberry Coming.—The Banquet.

The *American Agriculturist* has long urged that the growers of new strawberries should work in the direction of high quality, rather than in that of large size. No one wishes to be obliged to cut a strawberry in order to eat it conveniently, and we already have a sufficient number of varieties, the only claim for which is stated in inches of circumference. Mr. J. R. Hawkins, a successful cultivator of small fruits, at Mountainville, Orange Co., N. Y., submits to our inspection abundant specimens of a new strawberry which he calls the "Banquet." The origin of this new berry is stated by Mr. Hawkins in substance as follows. In 1880 he had a bed of that high-flavored, but rather dry variety, "Miner's Prolific." Some of the runners of this had made their way into a fence row, where our native wild strawberry (*Fragaria Virginiana*), was growing. Two or three of the largest berries of "Miner's Prolific," from the plants closely associated with the wild ones, were selected. The seed from these were separated, and sown in a box of earth, placed where it would receive the sun during the early part of the day. Some thirty or forty seedling plants had made their appearance in September, which were transplanted to the open ground in October. Unfortunately the hens undertook the cultivation of the patch, and with the usual result. The uprooted plants were replanted, and all were left without protection the following winter. In the spring of 1881, one of the seedling plants threw up a flower-stalk, and in June ripened about half a dozen berries of moderate size, and of such excellent quality, that Mr. Hawkins was careful that all the runners it made should take root. These gave him about six plants, which were set out in August. In 1882, about a quart of berries were borne by these plants, which were submitted to several well-known pomologists, who at once pronounced the fruit to be "one of great promise." The runners from the plants were pot-layered, and the plants, about fifty, were set out in September. These, in 1883, bore about fifteen quarts of berries. The same year Mr. Hawkins exhibited the berries in Boston, where the Mass. Hort. Soc. awarded it the premium for the best new seedling. We have been thus particular in giving the details of the production of the "Banquet," in order that they

may serve as a guide to others who wish to undertake the production of seedling strawberries. Mr. Hawkins states that the plants have each year increased in productiveness, and in the size of the fruit. This year berries were produced measuring an inch and a half in diameter, which is certainly large enough. The berries sent us were of uniform conical shape; while a few are shouldered, none are of the cocks-

THE "BANQUET."

comb form. The fruit is perfectly ripened at the end opposite to the stem. The color is of a rich crimson, without that tendency to turn black, so unfortunate in some varieties. We are informed that Mr. Charles Downing, noted for his caution in expressing an opinion, has stated that he regards the "Banquet" superior in flavor to the berry which bears his own honored name—high praise indeed. After carefully testing the "Banquet," we accord it a place among the highest flavored strawberries. The exquisite flavor of the wild fruit is so marked, that we can readily believe that this is due to a crossing with the wild plant. Mr. Hawkins' course in regard to sending out his new seedling, is to be highly commended. Many berries with not a tithe of the real value of this, have been heralded far and wide as the coming

berry. Mr. H. declines to place the "Banquet" on the market, before it has been fully tested by further culture. He expresses his regrets that it is not possible to have a committee of the Am. Pomological Society report upon the merits of new fruits, and adds: "I have a strong aversion to letting the 'Banquet' go out before some such thing is done, deeming that some action of this kind is needed for the protection of the public."

A New and Serious Strawberry Pest.

Mr. Samuel G. Wynant, Rossville, Staten Island, N. Y., a successful strawberry grower for twenty years, informs us that this year his crop has proved almost an entire failure, owing to the ravages of vast numbers of a small beetle. Specimens being submitted to us for examination, we have discovered them to be the same insect mentioned by Prof. Cook, State Entomologist of Michigan, as new to that State, viz., the Strawberry Weevil, (*Anthonomus musculus*). Now for the first time this beetle appears as a serious enemy to the strawberry, though it has been known to scientists for some years, having been described by Say. The readers of the *American Agriculturist* will be kept fully posted as to its progress. There are several species of this genus *Anthonomus*, closely resembling each other; in fact, the samples brought us by Mr. Wynant contained at least two species of these nearly related little weevils. The beetle is about an eighth of an inch long, and varies in color from a dull-red, to almost black. The wing-cases have impressed lines, bearing a few scattered dots. In the accompanying engraving the weevil is shown much enlarged, with hair lines to the right indicating the natural length. Very little is known of the habits of this new enemy to the strawberry, and its ravages this season suggest it as a subject worthy of the immediate attention of entomologists. Until the natural history of the insects is known, we can only mention remedies to be applied to the devouring beetles. The weevils feed upon the floral parts when the strawberry plants are in bloom, and also pierce the fruit-bearing stems, causing them to break off with their partly formed berries. In using any insecticide, it must be remembered that it is unsafe to use substances poisonous to persons. Paris Green and London Purple may be safely used on young apples to kill the codling moth worm, but to dust or spray a fruiting strawberry bed with a compound of arsenic, would be running too many risks. An emulsion of kerosene or petroleum, a formula for which was recently given in the *American Agriculturist*, may prove a satisfactory remedy. Pyrethrum powder is an excellent insecticide, and experiments should be made to prove its value in this case. After the life history of the weevil is fully known, it may be found easy to destroy this enemy in one or more of its earlier stages of development. It is hoped that the destruction which has come to the Staten Island berry fields, may not be repeated there, or visit other localities in coming years. Some of our insect enemies come and go, while others remain and continue to destroy as long as their favorite food-plants are grown, unless fought with a tireless vigilance. Mr. Wynant observed a few of the weevils on his strawberry plants last year. This fact leads us to suggest that it may be best to burn over with straw, and plow under the ruined fields, and if possible begin strawberry beds elsewhere, or grow other crops and attempt to starve out the troublesome weevils.

This beetle must not be confounded with another, which, though destructive, works in a different manner. We refer to the Strawberry Crown-borer *Tyloclonus fragariae*. This beetle is a trifle larger than the one above figured, and is brown, with darker brown spots. It lays its eggs upon the crown of the plant, and the larva, when hatched,

STRAWBERRY WEEVIL.

eats its way into the crown, upon which it feeds and kills the plant. Digging up the infested plants and burning them is the only sure remedy. Subscribers living elsewhere will please report ravages of the new strawberry pest, if any occur.

A Silk-Worm Cocoonery.

Any cheaply constructed outbuilding will answer for rearing silk-worms, if it be not near to any bad odors, and can be easily ventilated and heated. If the building is old, it should be thoroughly renovated, white-washed, and perfectly dried before receiving the worms. For household culture, a room eighteen by twenty feet, with two movable shelves extending around the room, two feet apart,

A SILK-WORM RACK.

will safely accommodate sixty thousand worms. A building eighteen by thirty-six feet, ten feet high, with four windows and two doors, will house two hundred thousand to two hundred and fifty thousand worms without crowding. Each cocoon rack is fourteen feet long, by five feet wide. There are six uprights, *a, a*, seven feet high, two inches wide, and one inch thick, mortised into the top and bottom of the frame. Stout nails, *b, b*, are driven into each upright, five inches apart, for holding the lath platforms, *c, c*, by which the worms feed. These racks can be taken apart and stored away after the feeding season is over, while the cocoonery can be used the remainder of the year for many other purposes. The trays, *d, d*, are placed on the platforms and used for feeding the young worms until after the second moult, when laths are laid crosswise over the rails, *e, e*, and branches laid on the laths. The lowest rods rest on the nails driven into the uprights, eighteen inches from the floor. As the branches accumulate on this platform, long rods with laths are laid on every fifth nail from the bottom. The worms will crawl upon the fresh leaves placed on the upper platform, and the lower rods may be drawn out and the litter removed. The worms may be carried to the top of the frame in this manner, and by that time they are ready to spin. When the cocoons are to be gathered, the spinning frames can be taken down. This is the most economical, convenient, and healthful arrangement for raising silk-worms that has been constructed.

The cocoonery should be well ventilated during the greater part of the season, and more especially during warm, sultry weather, the windows and doors need to be kept open night and day.

The sun should not shine directly on the worms, nor should they be exposed to drafts or sudden changes of weather. On damp, cold days, a little fire in the cocoonery will be needed. The natural laws governing the existence of the worm should be imitated as closely as possible.

The trays, *d, d*, used for feeding the young worms are made of laths nailed together. Full length laths are used with half lengths for the ends and center pieces. Small nails or tacks are driven in the edge half an inch apart, and twine is wound around each nail, passing across the frame both ways. Heavy brown paper with holes of different sizes, will answer for the bottom of the trays, in place of the twine. Twine trays may be used for feeding the worms, and for spinning, which adds to the convenience of gathering the cocoons. By loosening the twine at one end, and taking it back and forth from the nails, the cocoons can be stripped off in one half the time that it takes to gather them from among the branches, and there is less danger of bruising them.

Animal Ailments.

PROFESSOR D. D. SLADE, HARVARD UNIVERSITY.

HOG CHOLERA. SWINE PLAGUE.—A. A. Eaton, Lackawanna Co., Pa.—Your description of the symptoms exhibited by the sick swine faithfully portrays the course of swine plague. "The symptoms are as follows: first, a dull, sleepy feeling accompanied by a cough, which increases from day to day, and an entire loss of appetite after the first day. The ailment affects the small of the back (the spinal system of nerves), so much so that the hog, in most cases, loses the use of its hinder parts, but in a few instances it can get up and down until death. Later the animal breaks out on the belly and around the throat, with red blotches which increase in size, until they cover the entire belly from under the chops to the tail. They are purplish-red, and look almost like mortification. The hog dies in from three to eight days. So far none have recovered. With two, great emaciation accompanied the disease, but in the other cases they remained plump."—This is a highly contagious disease. By no means expose any newly purchased animals to the poison. Kill the sick and deeply bury all carcasses. Disinfect by efficient means everything that has come in contact with them. Use Carbolic Acid, Chlorine, Chloride of Lime, or Cop-peras. It would be far better not to occupy the same piggery under any circumstances if it can be avoided, certainly not until it has undergone a thorough and long continued purification. Place any newly purchased animals under strict quarantine long enough to prove their healthy condition. Avoid communication between these and the former herd by the same attendants.

GNAWING THE WOODWORK.—Jno. W. Hall, Hancock Co., Me.—Has a mare which "eats up her crib and everything that she can reach, is fat, feeds and works well."—It is often difficult to ascertain the cause of this propensity. It may depend upon irritation of the teeth and gums, or upon habit, which is the result of confined idleness, or again, the animal may find something in the wood congenial to its taste. We are not treating here of crib-biting as a vice. Whatever may be the cause, the remedy is to provide no wood-work for the animal to gnaw. Place the mare in a box stall with perfectly smooth sides and no projections. Feed grain from an iron manger, and hay from the ground. Give salt, and a chance to eat earth, plenty of exercise, and a variety of food at all times.

FEEDING OF HORSES.—E. Higgins, Norfolk Co., Mass.—Corn and oats should not be ground together in equal quantities, and given as food to the working horses, for the reason that the corn contains twice as much oil as the oats, has marked heating qualities, and being such concentrated food, is liable to produce colic and indigestion. To be sure, there are many horses on slow work that may become accustomed to a mixture of equal parts of oats and corn, and may escape any evil consequences, but still there is always danger. It is better to err on the safe side, and to feed a mixture, in which the oats exceed the corn by just double the amount.

SPLINT.—Mr. B. Moore, Greene Co., N. Y.—Splint is a bony enlargement or tumor, which in its formation causes pain and consequent lameness by the distension of the covering of the bone. This covering is extremely sensitive when at all inflamed. Sometimes the growth is very gradual, and the neighboring tissues accommodate themselves to the abnormal condition without causing pain and lameness. The size of the splint is no criterion of its importance, a small one often giving more trouble than a large one. The treatment in its early stages consists of subduing the inflammation by rest and cooling applications. After all heat and tenderness have gone, blistering is of service, which is to be repeated if the enlargement continues. If pain and tenderness return after an apparent cure, give the animal a long rest. It is not advisable to perform any surgical operation for the mere purpose of removing the tumor, as such an operation may induce an undue amount of inflammation in the parts. The tendency of the splint is to become absorbed. Hence it is not often found upon aged horses. The ointment of the Red Iodide of Mercury often proves an excellent absorbent of the bony tumor, a small portion to be rubbed in daily.

SHOULDER LAMENESS.—Mr. Reuben Davis, Columbia Co., N. Y.—From the symptoms given in your letter, I should say that the horse is suffering from shoulder lameness, the result of a sprain, or possibly of rheumatism, and that morbid changes were going on in the joints, in the course of which hony exudations will be thrown out. The presence of these changes undoubtedly account "for the snapping or cracking noise heard somewhere near the shoulder joint." For treatment, put on a high-heeled shoe, and turn out to pasture. Complete rest, or only very slow, light work, must be insisted on. Subdue any inflammation by warm water for mentations to the joint, to be frequently repeated.

Grandmother's Gingerbread.—A correspondent asks us for a recipe for gingerbread, "such as our grandmothers used to make." Our grandmother's granddaughter makes as good gingerbread as we ever saw, and this is the way she does it: Molasses, two cups; milk, one cup; flour, four cups; butter, one-half cup; soda, one teaspoonful; spice (cinnamon, cloves, or ginger), to taste. We have a notion that the best gingerbread is made without ginger.

Plant for a Name.—P. H. Adams, Williamson County, Tex. The plant sent, which you say the Cherokees call "Tonkawa," is *Gonolobus biflorus*. The genus *Gonolobus* belongs to the Milkweed (*Asclepias*) Family, and its species, usually climbers, are more abundant in the Southern than in the Northern States. But little is known about their properties, except that the roots of one or two are said to purge violently, and the Indians used the juice of some of them to poison arrows.

Our List of Fairs.—Already we receive applications for our list of the fairs to take place the coming autumn. We again urgently request, as usual, all Secretaries of Societies and Fair Associations, who have not already done so, to send us their announcements at once. Our publication of the list, gives each fair, however local, a wide advertising, which is worth taking a little trouble to secure. Let us have the announcements early!

A Curious Insect.—W. L. Remington, New Haven Co., Conn., writes: "I send by mail a curious insect, which I found under a stone in a moist place, and would like to know the name of it." The insect is the Northern Mole Cricket, *Gryllotalpa borealis*. Its name indicates its burrowing habits. This not very common insect was described and figured in the "Doctor's Talks" for November, 1881, page 493. There is another species in the Southern States, and one in the West Indies, which latter is said to be very destructive to the roots of the sugar-cane.

Rose-Bugs and Roses.—M. Stanford Jackson, Allegheny County, Pa., complains of the havoc the Rose-bug makes with his roses, and asks what he shall do to prevent their appearance on the bushes. The Rose-bug appears to defy the ordinary insecticides, and to require catching and killing. In early morning they are torpid, do not readily take to flight, and may be shaken from the bushes at that time. They may be caught upon cloths spread under the bushes, or in broad, shallow tin-pans, which contain a little kerosene. Those caught on cloths may be killed by kerosene or by burning.

Hurrying the Chicks.—H. J. Janzer having heard that there is an incubator that will hatch eggs in considerably less than twenty-one days, asks if it is true, and upon what principle such an incubator is constructed? We doubt if there is any method by which the time of incubation can be shortened an hour. In our experience with an incubator, we have found that those eggs which did not hatch within half a day after the twenty-first, did not hatch at all. The improper management of the heat may prolong the time for a few hours, but that any invention can be made to appreciably shorten it is, we think, very improbable.

Water Cresses.—Several who have suitable streams for growing Water Cresses, ask how to stock them with the plants. If Water Cress grows anywhere in the vicinity, the easiest way is to get plants or cuttings from an established bed. A fragment, or branch of a plant will grow readily. If plants are not available, they must be raised from seeds, which are kept by the principal seedsmen. The seeds may be sown in pans or shallow boxes, keeping the soil quite moist. When the seedlings are up, water freely, keeping the soil in the condition of mud. If exposed to full light, with plenty of water, the plants will grow very rapidly, and soon be ready to set out in the water beds.

Fertilizer for Strawberries.—C. O. Foster, McKean Co., Pa. Superphosphate of Lime, made by treating bones with sulphuric acid, would no doubt be useful for strawberries, though we should prefer thoroughly decomposed stable manure, or if a special stimulating fertilizer is required, guano, or ashes. If it is proposed to use superphosphate, buy it, but do not

undertake to make it. To one without experience in such manipulation, the operation of treating bones with sulphuric acid is a dangerous one, and has resulted in serious accidents. Farmers can make many things cheaper than they can buy them, but superphosphate is not one of these.

Above-ground Cellars.—The subject of building cellars above ground and apart from the dwelling, is evidently engaging the attention of many persons. Mr. H. W. Pond, New York City, writes us a number of suggestions concerning the building of such a cellar, one of which seems of special importance. He says: "I should make the first, or lower floor, of asphalt, and the foundation walls should have a stratum of asphalt laid in them at the level of the floor, to prevent the ascent of moisture." Also, "the asphalt or cement floor," he suggests, "should be sloping, and seepers made, so that, for sanitary reasons, it could be flushed with water." Mr. P. also suggests, that such a cellar should have an ice-chamber at the top.

Tomatoes and Cancer.—"Old Subscriber" writes: "I have two acquaintances who are afflicted with cancer. They have both been advised by their physicians to discontinue the use of tomatoes, either cooked or raw. Will you kindly give your opinion on the tomato and cancer question?" The statement that the use of tomatoes will cause cancer, has been the rounds of the press like many other loose assertions. We have not seen it stated by any responsible authority that the tomato has any relation to cancer. Secondly, we should wish to know, who decided that the friends in question are afflicted with cancer. Not one case in ten of so-called cancer is really that terrible affliction. For ourselves, we shall continue to eat tomatoes.

What Effect has Salt Upon Animals?—This question comes to us frequently. There is a small body of "reformers" who hold that the use of salt is the cause of many human ailments, as well as the diseases of our domestic animals. The necessity for salt in the human system was recognized in the ancient laws of Holland, which condemned criminals to be deprived of salt in their food, and they died in the greatest torture. Wild animals, especially deer, show that they regard salt as necessary, by travelling great distances in order to reach the "salt licks." Domestic animals show by the avidity with which they dispose of the salt at the periodical salting, that it meets a want of their systems. We should regard these manifestations as proof that animals needed salt, and that it was in some way beneficial. Physiologists tell us that the blood contains a large per cent of salt, and that this is necessary in order to keep the blood in its proper condition.

Meal Worms.—S. B. Doane, San Francisco Co., Cal., asks us: "How can I keep a stock of 'Meal-worms', in what must I keep them, and on what should I feed them, that they may multiply fast?"—There are two caterpillars called "Meal-worms," the parent insect of one being a beetle, and of the other a small moth. The worms are often found in old flour barrels, in Indian and rye meal, old ship bread, etc. They are used as bait in fishing, and especially as food for singing birds. If the worms are not full grown, we should keep them on Indian meal. There is no treatment by which our correspondent can multiply them, as in their caterpillar state they do not breed. They must pass into the state of pupa or chrysalis, from which they will come out as beetles, or moths, as the case may be. These are the perfect states only in which do they breed. The perfect insects lay eggs from which the worms hatch, and live in flour, meal, etc., until they reach their full size, when the same round is again gone through.

Rats and Flies.—We have received from ladies, suggestions for keeping both these pests at a distance. We give these for the purpose of asking for wider experience. If the remedies are generally efficacious they should be more widely known. As to rats, we translate from Mary Hadlein's German letter, who says: "The best thing to drive away rats is the Peppermint plant; they can not bear the smell of it and disappear. We place it in the oats, rye, etc., when they are brought in, and also under the pig pen. Though we no longer have any rats, we keep on using the plant, lest a strange one might make us a visit." In absence of the fresh herb, a few drops of the Oil of Peppermint should be equally efficacious. As to flies, Mrs. L. L., who has had several years' experience in California, writes us: "In southern California every old Spanish residence is surrounded with the Castor Oil plants, and when the American residents are tortured with the 'July fly,' that rivals all flies in numbers and pertinacity, these Spanish homes have not a fly or a mosquito in them."

Stumps. — Saltpetre and Kerosene.—An item went the rounds of the papers a few years ago, advising to bore a hole in the stump, drop in some saltpetre, and fill the hole with water. The next spring the hole was to be filled with kerosene, which, on being lighted, would consume the stump to the very ends of its roots. Mr. S. C. Sweetser, Aroostock Co., Me., adds his testimony to that of others, to show the entire inutility of this process. He tried it two years in succession, and the stump, which stands high upon the river bank, remains, to hundreds yearly, a prominent land-mark. Dynamite, or gun powder, would no doubt dispose of the stump. But why not, as it interests travellers by the river, let it remain? . . . Mr. J. A. Conkling, Baltimore Co., Ind., writes that he tried the saltpetre method on thirty or forty stumps, "and in every case failure was the result." He tried dynamite cartridges, placed in a hole made under the stump with a crow-bar. After the match was lighted, "there was a large hole in the ground, and the stump in the form of kindling wood." . . . Thos. P. Jones, Nova Scotia, adds, that he tried the saltpetre and kerosene method, and "the stumps are as sound as ever."

A Home-made Fruit Picker.—J. Ely, Kane Co., Ill., asks, if we have given an engraving of a good, home-made Fruit Picker. We have, first and last, given a great number of fruit pickers, but perhaps none better than one proposed by J. H. Ten Eyck, Cayuga Co., N. Y., who kindly gives every one the privilege of making and using it. A make-shift picker may be made from an old tomato or similar can. Cut some notches in the upper edge of the can, fasten it to the end of a stick of convenient length, and put a lock of hay in the bottom of the can. Mr. Ten Eyck's can is a bottomless dish, three inches high, five inches across at the top, and three and a-half inches at the bottom. This dish has a socket, by means of which to attach it to the pole. Above the socket project two stout wires close together below, and spreading above, to detach the fruit. To the bottom of the dish is a long, bottomless bag of cotton cloth, of a proper width, to be tied to the bottom of the picker. This bag, or hose, should be about two feet longer than the pole. By means of this, fruit upon the outside of the tree, always the largest, can be detached, and sliding down the cloth channel, may be caught and conveyed to the basket without bruising.

"How is Corn Hybridized?"—J. S. Harmon, Madison County, Iowa. In answering the above questions, as we, of course, have no means of knowing how much the questioner understands of the fertilization of plants, we are obliged to assume that he knows nothing. The majority of people are aware that there are two parts of the flower concerned in fertilization, the pistil, the part to be fertilized, and the stamen to furnish the fertilizing principle, the pollen. In our fruit trees, in the bean, pea, the tomato, and many others, these parts, the stamens and pistils, are in the same flower. In squashes, cucumbers, and all of that family, the stamens are in one set of flowers and the pistils in others, but on the same plant. If the bees and other insects did not carry the pollen from the staminate, or male flowers, to the pistillate or female flowers of these plants, these latter would not be fertilized. In corn, the two kinds of flowers are upon the same plant. The flowers of the tassel are staminate only, and produce pollen. The pistillate flowers, very simple in their structure, are closely set upon a short stem, the cob, and are surrounded and protected by leafy bracts, the husks. Each one of these flowers has a long, slender, thread-like portion to its pistil (the style), which extends from even the lowest flowers on the ear to the top, and there those from all the flowers hang out as the silk. The end of each thread of silk (stigma) is especially adapted to receive the pollen and convey its influence to the part of the pistil (ovary), which will in time form the grain. No insects are required by the corn to convey the pollen. The pistillate flowers, in the ears, are placed where the pollen from the tassel will fall directly upon them. But it often happens that, just at the critical time, when pollen is falling, a wind may blow. The wind may carry a part, at least, of the pollen away from a corn plant, and bring pollen from a distance, from another kind of corn. This wind-brought pollen, falling upon the pistils of our corn, will cause a mixture, or as our correspondent would say, it will "hybridize" it. As our varieties of corn are all forms of one species, the term crossing is better than hybridizing to apply to the fertilizing of one variety by the pollen of another. It is in this manner, by the aid of the wind that accidental crossing or mixing takes place. It may be that Mr. H. wishes to cross or hybridize two varieties intentionally as a matter of experiment. In that case he must plant both varieties near together. As soon as tassels appear upon the stalks of the kind selected for seed-bearing, they should be cut away before the flowers open. The ears upon these stalks will receive the pollen of another variety, and the seed will be a mixture.

Chat with Readers.

How He Treats Ants.—S. C. Sweetser, Aroostock Co., Me., says: "Tell your readers if they are troubled with ants, to open the hills, pour in a little gas tar, and the ants will leave or die."

Pine Saw Dust.—"R. M. G." asks, if well rotted pine saw-dust has any value as a fertilizer.—In itself the saw-dust can have little or no value. It might be useful to dilute and dilute some active fertilizer, in the same manner as peat and muck are used, though not so useful as peat and muck.

Trouble with Plums.—H. H. Miller, Westchester Co., N. Y., writes us that he has three large, thrifty plum trees, which bloom every year, but soon after the blossoms drop, the little plums fall also. Not a dozen plums have matured upon the trees.—We cannot guess in this case. Specimens should have been sent.

Robins and Cherries.—F. Perrin, Dutchess Co., N. Y., asks, how robins and other birds can be prevented from taking all his cherries.—The only effective way, so far as we are aware, is to protect the trees by means of nets. In England, netting is sold for the purpose. In this country, old fishing seines, not strong enough for their proper use, have been employed.

Grass for a Name.—M. Haggard, Harrison Co., Tex. The specimen of the vigorous grass you send, is no other than the much talked of Chess or Cheat (*Bromus secalinus*). There are people who believe that this grass is a degenerate wheat, as it is often found as a weed among wheat. This is no more likely to be the case, than that your Jack-ass Rabbit is a degenerate Burro. As a fodder it ranks very low, and the grass should be treated as a weed.

Red Ants.—T. C. Underhill, Orange Co., N. Y., asks us to how get rid of red ants.—The best method we ever tried was to smear the surface of plates with lard; these are to be set on shelves, etc., and small bits of stick or chips laid from the edge of the plate to the shelf, to form bridges or causeways for the insects to ascend. When a large number are caught, seal them, and set the trap again. Insect Powder (Pyrethrum), is said to kill them, but we have not tried it.

A Hay Twister Wanted.—In parts of Dakota, and other far western localities, wild hay is used for fuel. Mr. E. A. Forbush, Kingsbury Co., Dakota, hopes that among the many useful contrivances published by the *American Agriculturist*, some one will contribute a hay-twister, "a cheap and durable machine to save time and labor."—Any one having a twister in use, will please send a drawing, however rude, and description, to help our Dakota friend.

Hungarian Grass.—W. T. Coolbridge, Spink Co., Dak. Ter., and others.—Hungarian grass rightly managed, is most valuable, whether for green fodder or for hay. It needs land in good condition, and six weeks of good growing weather, with warm nights. Sow a bushel of seed to the acre—some sow a bushel and a half. The most important point with this grass is to cut it early enough. Cut when the heads are in flower, before the seed begins to form. If cut too late, the bristles that surround the grain become hard, and have been known to injure horses.

Keeping Early Apples.—J. L. Porter, Seward Co., Neb., asks us how early apples can be kept until the time of autumn fairs, other than in jars of alcohol.—The fair authorities do not regard that in alcohol as fresh fruit. Strong brine, and a mixture of glycerine and water will preserve the fruit, but there would be the same objections to these as to alcohol. Probably if the fruit were picked while yet hard, and packed in tight boxes, which were placed in an ice-house, they might keep. The experiment is worth trying. Fruit so kept would perish soon after being taken from its cool storage.

A Deposit of Lignite.—Mr. L. A. Page, Baltimore Co., Md., sends us a sample of Lignite, a vein of which was found in digging a well. He asks if it has any value as a fertilizer.—Lignite is wood, more or less completely converted into coal, and at best has no more fertilizing value than charcoal. If it could be dug without cost, and exposed to freezing, it would probably be converted into a fine powder. In that state it might be used as an absorbent in stables, etc., and then used on the land. Its value would depend almost entirely upon the matters it had absorbed. For this use, it would not pay to dig for it if much below the surface.

A Rare Tree in His Neighborhood.—Michael Hege, Franklin Co., Pa., having found a tree new to him, transplanted it to his yard, where it grew so finely that he wishes to know its name.—The leaves and fruit show it to be the Ash-leaved Maple, also called Box Elder (*Negundo aceroides*), and is common along the banks of the Western rivers. Its rapid growth and regular shape, make it valuable as an ornamental tree. Its wood is much like the Red Maple; it is valuable to plant for fuel on account of its rapid growth. Sugar is made from its sap. The tree is raised from the seed, which is often abortive. The seed ripens in the fall, and should be kept through the winter in sand, and sown in spring.

Trouble with Currant and Snow Ball Bushes.—W. Angus, Douglas Co., Minn., sends us specimens of leaves, upon the underside of which are numerous small insects, and "the leaves curl up around them."—The insects are one of the many kinds of plant lice. Most of the plant lice are readily destroyed by tobacco water, and these would probably yield to the same treatment. A pound of tobacco stems, removed from the leaf by cigar makers, or other cheap form of tobacco, may be steeped in water.

When the liquid is of the color of black tea, apply it by means of a syringe with a curved pipe, that will allow the lower side of the leaves to be reached by it. . . . The same answer is made to C. H. Carlton, Chicot Co., Ark., who sends plum leaves attacked by plant lice.

Orchard Grass.—H. F. Juneman, Mercer Co., Ohio. The strange grass found in your friend's meadow is Orchard grass (*Dactylis glomerata*), in England almost universally called Cocks-foot grass. It seems strange that this grass is so little known, as it is very often sent us, and from States much older than Ohio, to ascertain its name. In many respects Orchard grass is vastly superior to the popular Timothy, especially to sow with clover. Those who sell hay, do not sow it for the reason that purchasers will have Timothy, no matter how hard and woody it may be. It is worth while for every farmer not acquainted with Orchard grass, and that will include the majority, to look into its merits, and indeed into those of several other grasses, and see if it is to his interest to always raise Timothy for all purposes.

Peaches from Florida.—Messrs. Eppinger & Russell, New York City, send us specimens of two peculiar peaches, grown on their lands at Olmsted, Fla., upon trees only eighteen months old.—They were the Houey and Peen-to peaches, and both of Chinese origin. The Houey is small, oval, with a projection or beak at the end opposite the stem. The flesh has an intense sweetness. This is reproduced from seed almost exactly. It has been cultivated at the North by amateurs, but is too small for market. The Peen-to is the flat-peach of China, which we figured several years ago. It is remarkably flattened at both ends, the flesh being at the sides of the small stone, giving the fruit an odd appearance. The flesh is very sweet with a pleasant peach-stone flavor. This has ripened in Georgia, but we are not sure as to its hardiness in the Northern States.

Is Blood fit for Human Food?—P. Westrum, Hamilton Co., Iowa. Blood, containing all the elements of the flesh which is formed from it, is regarded as highly nutritive. On the other hand, if the animal from which the blood is taken be diseased in any manner, the germs of that disease are likely to be in the blood, and to communicate the disease to those who use it as food. This objection is answered by those who advocate the use of blood as food, by the assertion that these germs may be killed by cooking. Among Americans there is a general aversion to the use of blood, though their English ancestors were very fond of "black pudding," made with blood, fat, spices, and oat-meal. The Germans use blood largely in the form of sausage. If one wishes to make use of blood as food, we know of no reason why he should not do so, provided the blood is taken from healthy animals.

Surgery upon a Tree.—Mr. H. P. Hubbard, New Haven Co., Conn., has a favorite Horse Chestnut tree, which, having received some injury when young, had begun to decay. A portion of the trunk had rotted away, leaving a hole about eighteen inches long, and some six or eight inches wide and deep, and this was increasing in size. Wishing to save the tree, Mr. H. carefully dug out all the rotten wood, fixed some boards in front of the hole which was filled up full with cement, mixed thin enough to be poured in. The bark is now growing over the cement, and promises to completely cover it and conceal the injury.—We give this as a hint to others, who may have trees similarly injured, that they would like to save. Common mortar has long been in use for plugging up holes in trees; cement is doubtless much better. Success in the operation will largely depend upon the thoroughness with which the decayed matter is removed; only clean sound wood should be left.

Cut-Worms.—H. W. Martin, Windham Co., Conn., asks us: "Is there any way to get rid of cut-worms, other than to hunt and kill."—This is in brief the purport of many letters we have received this season. Dr. A. Oemler, of Georgia, having suffered severe losses from the abundance of cut-worms, tried various remedies. He gives the following as the best remedy he has found. Cabbage or turnip leaves are dipped in a mixture of a tablespoonful of Paris Green to a bucketful of water, which is kept well stirred. Another method of poisoning the leaves is, to first moisten them, and then dust them with a mixture of one part of Paris Green, to twenty parts of flour. The poisoned leaves are placed fifteen or twenty feet apart, both ways, all over the field, taking care to place the leaves prepared with the flour mixture, dusted side down. The Doctor quaintly remarks: "Two such applications, particularly in cloudy weather, at intervals of three or four days, will suffice to allow the cut-worms to make away with themselves, which they generally do with perfect success."

Castor Oil Beans.—Mr. R. B. Brown, the President of a large Oil Pressing Company at St. Louis, Mo., writes us with reference to an item in our columns. The company still loans seeds to farmers, and contracts to buy the crops either at a fixed price, or at the current rates at harvest time. There are, however, not at present any restrictions upon the trade in the beans, but they are bought and sold and consigned to dealers the same as any other produce. The prices at St. Louis the past spring and fall, have been from \$1.75 to \$2.00, and during the past fifteen years, they have ranged from \$1.00 to \$4.00 per bushel. There is always a demand for them at St. Louis, and the market requires about five hundred thousand bushels annually. Mr. Brown thinks that there are few products so useful to a farmer in a new country, or which, in the absence of railroads, he can so profitably haul a long distance to market, as the Castor Beans, which always bring ready money. In the printed directions sent for treating the crop by Mr. B., it is advised to drop eight or ten seeds in each hill, rather than two or three as stated by us, though but one plant is finally left.

A Bored-Well Bucket.

On the Western dry plains, where water can be reached only at the depth of from seventy to one hundred and twenty feet, the sinking of a well is no small matter. The well is usually bored, and a six or eight-inch zinc pipe inserted. No ordinary pump can be used, but water may be drawn by means of a "bucket," as shown in the engraving. The bucket, which is only very little less

BUCKET FOR A BORED WELL.

in diameter than the well-pipe, consists of joints of zinc-pipe soldered together, with a stiff bail at the top, and a valve at the bottom. The bottom itself is a circular piece of soft wood, usually pine, with a hole in the centre nearly two inches in diameter. On the upper side is a piece of stiff leather for a valve. *b* represents the bottom, on a larger scale than the bucket, and *a*, the leather valve. To stiffen the leather, fasten a convex block of wood on the upper side by means of a tack from beneath, and screw the whole by the

Dog Law.

A valuable shepherd dog belonging to a farmer in Northern New York, while crossing over a neighboring farm, got into an altercation with the neighbor's bull dog, and was so roughly handled in the fight which ensued, that he died in consequence. The owner of the shepherd dog wishes to know whether he can recover its value from the owner of the bull dog. He says that his dog had a gentle disposition, and was not given to fighting.

It is very doubtful whether, under the circumstances, the value of the dog could be recovered. At the English common law, dogs were not regarded as having intrinsic value, and they could not be the subject of larceny (4 Blackstone, 236). But this is not the present American doctrine, for there are now many cases in which damages have been awarded for the unlawful killing of valuable dogs (109 Mass., 273; 60 Ill., 211). In these cases, however, man has generally had a hand. The reported decisions involving the law of dog fights pure and simple, in which man has not been present as a modifying influence, are not numerous. There is fortunately one, a New York case, in which the facts were nearly identical with those above stated, and in that the learned judge discourses as follows:

"*The branch of law applicable to direct conflicts and collisions between dog and dog, is entirely new to me, and this case opens up an entirely new field of investigation. I am constrained to admit total ignorance of the code duello among dogs, or what constitutes a just cause of offense, and justifies a resort to arms, or rather to teeth for redress; whether jealousy is a just cause of war, or what different degrees and kinds of insult or slight, or what violation of the rules of etiquette entitle the injured or offended beast to insist upon prompt and appropriate satisfaction, I know not, and I am glad to know that no nice question upon the conduct of the conflict on the part of the principal actors, arises in this case. It is not claimed upon either side, that the struggle was not in all respects dog-like and fair. Indeed, I was not before aware that it was claimed that any law, human or divine, moral or ceremonial, common or statute, undertook to regulate or control these matters, but supposed that this was one of the few privileges which this

class of animals still retained in the domesticated state; that it was one of their reserved rights, not surrendered when they entered into and became a part of the domestic institution, to settle and avenge in their own way, all individual wrongs and insults, without regard to what Blackstone or any other jurist might write, speak, or think, of the 'rights of persons' or the 'rights of things.' I have been a firm believer with the poet in the divine right of dogs to fight, and with him would say:

Let dogs delight to bark and bite,
For God hath made them so;
Let bears and lions growl and fight,
For 'tis their nature to.

***Whatever may have been the character and habits of the victorious dog, there is no evidence that he was the aggressor, or in the wrong, in this particular fight. The plaintiff's dog may have provoked the quarrel, and have caused the fight; and if so, the owner of the victor dog cannot be made responsible for the consequences. There is no evidence that the defendant's dog was a dangerous animal, or one unfit to be kept. The cases cited, in which dogs have attacked human beings, although trespassers, and the owners have been held liable, are not applicable. It is one thing for a dog to be dangerous to human life, and quite another to be unwilling to have strange dogs upon his master's premises. To attack and drive off dogs thus suffered to go at large, to the annoyance, if not the detriment and danger of the public, would be a virtue, and that is all that can be claimed, upon the evidence, was done in this case. Owners of valuable dogs should take care of them, proportioned to their value, and keep them within their own precincts, or under their own eye. It is very proper to invest dogs with some discretion while upon their master's premises, in regard to other dogs, while it is palpably wrong to allow a man to keep a dog, which may, or will, under any circumstances, of his own volition, attack a human being. If owners of dogs, whether valuable or not, suffer them to visit others of their species, particularly if they go uninvited, they must be content to have them put up with dog-fare, and that their reception and treatment shall be hospitable or inhospitable, according to the nature, or particular mood and temper at the time, of the dog visited. The courtesies and hospitalities of dog-life, cannot well be regulated by the judicial tribunals of the land." (Wiley vs. Slater, 22 Barb., 506).

In Michigan there was a statute requiring the owner of every dog to procure a license for it, and keep it collared, and making it lawful for any person to kill any and all dogs going at large, not licensed and collared according to the provisions of the act. While this statute was in force, a large dog meeting a small but valuable one, and observing it not to be properly collared and licensed according to law, proceeded to execute the law upon it by killing it forthwith. The owner of the slain dog brought suit against the owner of the canine executioner, who endeavored to shield himself under the provisions of the statute. But the court said:

"*A statute under which a party is, in so summary a manner, to be deprived of his property, by having it destroyed, should not be extended by construction. That dogs have a value, and are the property of their owner, cannot be well denied at the present day, whatever may have been the rule heretofore. And without questioning the power or the State to prescribe such regulations as may be deemed necessary and proper to prevent injury being done by them, yet we cannot say that where the legislature has authorized persons to kill dogs found running at large contrary to the act, the authority thus given to persons can, by construction, be so enlarged as to embrace animals also.*" (31 Mich., 283).

The foregoing quotations indicate in a general way, the state of the law upon this subject. It is safe to say, that in the case of our inquirer, it is doubtful whether there could be a recovery of damages. The dog at the time of its injury was really a trespasser. It was at least out of its master's control, on an expedition of its own; and if its master allowed it thus to go about, he must take the consequences of such dog fights as it may engage in. It seems, too, that it matters not whether it is, or is not the aggressor in such fights. A dog has its right to drive other dogs off from its master's premises, and if in so doing it injures them, there is no liability on the part of the master. It would be different if the master himself injured the prowling dogs. A man has no right to kill a dog simply because he finds it on his premises, even though he suspects it has been doing mischief (60 Ill., 211). If the dog is known to be a ferocious and dangerous one, and is permitted to run at large by its owner, or escapes through negli-

gent keeping, its owner having knowledge or notice of its vicious disposition, then any person is justified in killing it (13 Johns, 311). So, also, one may kill a dog that has been bitten by a mad dog, or that for any other reason is dangerous to human life (17 Barb., 561), but this is the limit of the right. One cannot set traps for dogs, or leave poisoned meat for them, for in either case he will be liable if they are thereby killed (9 East, 277). Where two dogs get to fighting by reason of their propensity to fight, as dogs often do, it is safe to say that neither owner is liable for consequences.

Where one keeps a dog which he knows has a dangerous and ugly disposition, it is his duty to so restrain it, that no harm can come from its evil propensities. He will be liable if he fails to perform this important duty. And the rule will apply where other dogs are injured, unless it can be clearly shown that the injured dog was trespassing, or that it was engaged in a common dog fight.

A Wire Tightener.

Mr. W. Fulmer, Allegheny Co., Pa., sends us a model of a wire tightener, from which the accompanying engraving is made. It consists of a long

wooden lever, with two pieces of iron fastened to it, as shown in the ent. The ends of the iron parts facing each other are made rough, to firmly hold the wire, which passes between. Though similar wire tighteners are furnished by the wire manufacturers, we present this illustration in order to enable every farmer, who has not one, to make a convenient and serviceable tightener for himself.

Kill the Late Weeds.

The fight with the weeds in the corn-field should not stop with the cultivator. We have frequently seen farmers strive manfully against the pests until midsummer, and then, through negligence, subject themselves to annoyance through the next season. Some weeds have a limited season of growth, and if kept rooted out until midsummer, will rarely come up again; others continue growing until severe frosts come. An old Illinois farmer said a cocklebur would come up in the morning, grow until four in the afternoon, and mature seeds before the frost could kill it that night. This is an exaggeration, yet the cocklebur must be fought until there are heavy frosts. The velvet-leaf, Jimson, and rag-weeds, will commence growth almost as late. Weeds are very prolific, and an occasional one gone to seed in the corn-field, will insure a good crop the next season. Corn should not be cultivated after it is tasseled, but the weeds can be cut out without disturbing the soil. For this purpose we have seen a short scythe used, but we much prefer a hoe with a sharp edge.

A Plow Plank.

A convenient device for moving a plow from one part of the farm to another, is shown in the engraving. It consists of an inch and a half plank,

A DRAW PLANK FOR A PLOW.

one foot wide and eight feet long. The front end, *a*, is rounded so that it may slide along easily like a stone boat. A piece of stout chain, eighteen inches long, is fastened to the sides of the plank at *b, b*. The point of the plow is placed under this chain, and is held there when the team is moving. A man standing on the rear end of the plank, can hold the plow and drive the team. A plow thus "shod," will easily pass over a meadow or lawn.

The New York Fishery Commission.

ROBERT B. ROOSEVELT.

The first Legislative enactment in reference to the artificial culture of fish was passed in the State of New York in the year 1868. It was followed up in the succeeding year, that of 1869, by the creation of a Fishery Commission, consisting of ex-Governor Horatio Seymour, Seth Green and Robert B. Roosevelt. Mr. Green withdrew in order to accept the superintendency of the work, and Mr. Seymour subsequently resigned. The Board to-day is composed of Robert B. Roosevelt, the President, Gen. Richard U. Sherman, Secretary, Mr.

is \$206,131.93, including the sum paid for the hatchery house at Caledonia, and the fitting up of a subordinate establishment at Cold Spring on Long Island. For thirteen years there has been an annual distribution of fish—a year being required to commence operations, and one being lost by the veto of the appropriation by Gov. Cornell. During that time there have been hatched, and turned loose, in their native or other appropriate waters in this State, 55,554,300 shad, 11,519,000 salmon trout, 6,909,200 brook trout, 4,499,000 California trout, 45,300 hybrid trout, 2,000 Kennebee salmon, 678,000 California salmon, 18,000 land-locked salmon, 2,480,000 white-fish, 900,000 frost fish, 34,920 mature black bass, 3,000 mature pike-perch, 155,000

pulled down to give place to the more pretentious structure, shown in the engraving given below. The New York Commission can claim the credit for originating most of these discoveries. Mr. Seth Green seems to have a genius for applying the exact remedy for every need in fish culture, and he has been well seconded by his assistants, and especially by his brother, Monroe A. Green, who is one of the ablest practical fish culturists in the country. He discovered the process of dry impregnation, one of the first great strides in the art, and which was afterwards imported from Europe, whither he had contributed it as a scientific discovery. He afterwards invented the shad-hatching box, which contains the underlying principle of all subsequent

THE NEW FISH-HATCHING HOUSE AT CALEDONIA, N. Y.

Engraved for the American Agriculturist.

Eugene G. Blackford and Mr. William H. Bowman. The first work done by the Commission was the hatching of 2,604,000 shad, 280,000 salmon-trout and 1,000,000 white-fish in the year 1870. It was not until the year 1875 that the Commission was authorized to purchase a State Establishment and commence the breeding of trout. The place chosen for this purpose was the old hatchery which had once belonged to Seth Green, and where he had achieved his reputation and made the first real successes in fish breeding in this country. It had been sold to Mr. Collins, but as it was regarded as one of the most eligible sites in the State, for such an enterprise, it was purchased at a cost of fourteen thousand dollars, and put at once in efficient and practical, but by no means showy, order. The record of the tumble down shanties, and board-banked ponds, is far from a discreditable one, and will answer the question often and properly asked, whether fish culture has paid.

It was stated by the Hon. Theodore Lyman, at the last meeting of the Fish-Cultural Society in Washington that \$1,300,000 had been expended in fish culture in this country alone. If so, but a very small portion of this vast sum has been expended in the State of New York, and the larger part of it has been expended by the United States Commission, in scientific investigations, in displays at foreign exhibitions, in studying the habits of fish, in printing learned disquisitions on ichthyology, and in exploring the bottom of the ocean for new forms of piscatory life, all proper expenditures, but cannot in any way be construed into fish culture.

The amount of money expended by the New York Commission from the year 1868 to 1883 inclusive

sturgeons, beside other minor fish. The first distribution of brook trout was made in 1874, when the Establishment that was afterwards purchased was leased with a view to its subsequent acquisition.

The California or rainbow trout all came from one lot of three hundred eggs purchased in California from a private individual, and received not in the best of condition. The first distribution was made in 1879, and some of the original stock are still living, and promise to keep up their fertility. The hybrids are a cross between the lake trout and brook trout, and promise an improvement on both species. They have shown themselves to be abundantly reproductive, although, among the eggs, are found more unimpregnated ones than among the pure breeds of either species.

The Kennebee salmon did not seem to be wanted in any part of the State, and so, although many were hatched, they were turned loose in Caledonia Brook, and no account was kept of them. Little was done with California salmon as it was not found, in a single instance, that they survived their journey to the ocean, or returned to their place of birth. The black bass and allied species are not hatched at all, they are distributed to new or depleted waters. It is found that they can attend to their own reproduction as well as it can be done for them. They have the instinct not only of building their nests, but of watching over and bringing up their young. Indeed it is doubted whether black bass fry could live unless they had the care of their parents. A few pairs of black bass will stock a lake or river if they are not fished out for a few years.

Immense strides have been made in fish culture since the old house was built, and before it was

modifications of hatching jars, boxes, or implements, taking the idea of the upward motion of water rising from a spring as its foundation theory. Mr. Green introduced the use of layers of trays instead of placing single trays one beside the other, and invented the carrying-box with flannel drawers for the transportation of eggs, the methods of packing eggs still in vogue, and a thousand and one minutiae, many of which have been imitated and claimed by others. To-day, now that the ancient time-eaten, bug-bored and weather-stained shanty has been replaced by a reputable building, with some pretensions to architectural attractions, and the ponds have been rebuilt with walls which will hold water and trout securely, and in spite of the fact that the State owns no individual right of entrance, and not half enough ground for ponds, there is no establishment in the world where as good work is done as at the hatchery at Caledonia.

Farmers should bear in mind that water-culture can be made a part of agriculture, not that it is expected that farmers should devote their time to hatching the eggs of trout, or of any of the more tender varieties, or of necessity to the hatching of any eggs at all, if they have not the special taste and the leisure, but where there are streams on, or adjoining the farm, they should give their attention to introducing the proper kind of fish, especially such as one of the different species of bass. These will increase rapidly, and take care of their own young, and by devouring useless varieties, will supply food for the table, to say nothing of that which most of us enjoy, a day's sport with the rod. Such fish and full instructions can always be obtained from the Superintendent at Caledonia.

Improvement in the Quince.—Meech's Prolific.

From very early days in the history of fruit culture, the "Apple-shaped," or "Orange" quince, and the "Pear-shaped," were the only varieties of the quince regarded as the best for fruit, while for stocks upon which to graft the pear, the "Angers," and one or two others, were commended. These sorts for a long time made up the rather meagre list of quinces. Indeed, it was only when American seedlings were brought to notice, that there was any improvement in the quince. "Rea's Mammoth" was so much larger, handsomer and better than any of the old varieties, that it convinced people that the quince was capable of great improvement, and other new varieties since introduced, have been regarded with favor. Notable among them, are the "Champion," described in these pages when it was first offered, and "Meech's Prolific." All that is known about the history of the variety is, that one of the early settlers in Vineland brought the tree from Connecticut. It then had no distinctive name. The tree finally fell into the hands of Rev. W. W. Meech, of New Jersey, whose long and practical experience with quinces has enabled him to both instruct and entertain our readers. He planted it with his other varieties in order to test it, and it proved to be superior to all. The tree is readily propagated from cuttings, grows rapidly, and comes into bearing very early. Out of two hundred and eight trees propagated last year (1883), fifty-seven bore blossoms the past spring. There is abundant evidence that the variety is properly named "Prolific," as the fruit is so abundant as to require severe thinning. The flowers are unusually large, making the tree when in bloom very ornamental. The obscure pyriform shape of the fruit is shown in the engraving, which is one-third reduced. The fruit is large, those weighing twelve to fifteen ounces are not uncommon, and they have been known to reach eighteen ounces. Eighty average quinces of this variety make a bushel. The fruit is at first covered with a dense whitish down, which protects it from many insect enemies, and when ripe is of a fine orange yellow, with a delicious fragrance. As to the quality of the fruit, there is abundant testimony from those who have tried it. One writer says: "It cooks as tender as a peach." While its leading characteristic is its prolific bearing, this variety, it is claimed, possesses in the highest degree, all other qualities that go to the making up of a first class quince.

Cats on the Farm.

Cats ought to have an honored place on the farm, but too often they have no place at all. This is because they are kept at the house, fondled by the pet-loving children, and fed by the kind-hearted women until they become lazy and worthless. The farmer esteems cats less highly than dogs; but the former are sometimes of the greater value to him. Barn cats should rarely be allowed to come to the house, and never be fed there. All that they need is plenty of milk; compel them to get the rest of their living, and they will find it about the barn, granaries, cribs, sheds, and in the fields. A good mousser is worth ten cents per day about a granary, crib, or barn. Mice not only destroy grain, but make it filthy for stock; they nibble sacks and im-

plements, and do much other mischief. A good cat will destroy large rats as well as the young ones. We have an old Maltese Tom, which gets his living by catching ground-mice in the orchard and garden, and is therefore a valuable cat. At this season, when barns, granaries, and cribs are filled, a cat is doubly useful. Give Tom and Tabby a fair trial, and you will always keep cats. S.

Do Not Gall the Horses.

The rush of mid-summer farm work is very trying on horse-flesh. The side draft of a reaper or mowing machine frequently causes galled necks and shoulders. The usually tough skin of the horse is softened by the flow of perspiration, and a rough, ill-fitting collar, a useless, chafing back-pad, or a projecting buckle quickly produces pain.

A NEW PROLIFIC QUINCE.

No one can blame a horse for faltering, when ordered to press its raw and bleeding shoulder against the collar, that will sink into its bruised flesh. To avoid galls, all parts of the harness should fit closely. A laboring man is careful in buying boots of proper size. He could not endure twelve hours of hard labor while his feet were cramped within an unusually small space, or in boots so large that his feet slip in them and wear the skin away by constant friction. As a rule, horses are worked in too large collars. A soft pad placed under such will prevent galling. When the animals are brought in from work, the harness should be removed at once and cleaned, and the necks and shoulders well washed with castile soap and water. After bathing the worn parts at night, rub on some softening oil. Use no oil in the morning. The collar should not be oiled, as it will then gather dirt through the day and form a rough coating, that will chafe the exposed parts. Keep all parts of the harness clean, especially those that press upon the horse, and see that the same is true of the portions of the horse against which the harness presses. It is much easier to prevent than to cure a gall.

Feeding and Care of Farm Animals.

PRIZE ARTICLE.—BY "A WESTERN FARMER."

It is a curious fact that almost every farmer who keeps five or six kinds of stock, gives nearly his whole attention to one or two of them. A man who is fond of horses and cattle, cares little for sheep or hogs; one who likes sheep and hogs knows little about poultry; one who takes pride in his poultry, pays little attention to horses and cattle, and so on. Farmers who thoroughly understand the care of horses, cattle, sheep, hogs, and poultry, feel an equal interest in each, and can make all profitable, are not as common as they should be in this or any other country.

Horses.

STABLE.—The horse stable should be warm in winter, and cool in summer; light, well ventilated, and so arranged that it may be darkened, and have wire screens over the windows to exclude flies. The floor, whether of plank, ashes, or other material, should be dry, and slope back gradually from the manger. The manger and feed-box should be grain tight, with bottom, at least, a foot above the floor. In fly time, darken the stable when the horses are taken in—close the doors and open the windows. Rest and comfort is thus assured, and their value to working horses can not be given in dollars and cents.

FEEDING.—Intelligent observation and practical experiment enable the owner to ascertain how much food a horse should have. Of two horses, of equal size and weight, one may require one-third more food than the other, to keep it in equally good order and working condition. When at steady work, the morning meal may consist of cut hay, and shelled corn and oats mixed; the noon meal, oats and corn, and a little cut hay. At night, feed two-thirds as much oats and corn as at other meals, a few pieces of carrots, and as much uncut hay as the horse will eat. When at rest, feed lightly—just enough to keep in good condition; mostly oats and uncut hay. Clean out the manger and feed-box before each meal. Clean, bright timothy hay is superior to any other for horses. If cut just before blossoming, well cured, and stored in a dry place, it will be devoid of that fine, pungent dust—the pollen of the flowers—found in it, when cut in full blossom. If at all dusty,

it should be dampened when fed. In case there is no barn room available for storing, it will pay one hundred per cent on the cost, to erect a shed twelve feet wide, and twenty to thirty feet long for it. The floor may be strong poles or rails, resting on block or brick pillars, eighteen inches high. Oats should be clean and dry, never musty, and fed to working horses in combination with shelled corn. For horses at rest, they may be fed alone. Corn should be well ripened, kept dry, and shelled as fed. It should be mixed with oats, in the proportion of one quart of corn to two of oats. Corn on the ear is productive of lamppass, and if the horse has defective teeth, much of it is swallowed without being properly masticated, producing flatulence and colic. One or two carrots cut fine, and mixed with the evening meal, are very beneficial in the absence of grass, as they tend to keep the bowels open and regular. They are most excellent for horses in winter and spring. Bran is a useful article of diet. Wetted, mixed with half its bulk of oats, slightly salted, and fed twice a week, its effects are very beneficial, especially to carriage horses.

Kentucky Blue-grass (*Poa pratensis*) makes the

best horse pasturage in the world. The next best is a mixture of Orchard-grass (*Dactylis glomerata*), Red Top (*Agrostis vulgaris*), and Meadow Fescue (*Festuca pratensis*). Turn horses into the pasture at every opportunity. Nothing does a dry fed, steadily worked horse more good than a few weeks, or even days, on grass.

It is very important that the drinking water be pure. The well should not be in the barn-yard, or it is certain to become polluted. Good cistern water is best, if it can be obtained. Water before meals. If the horse is very hot, give half a pailful; feed uncut hay and rub down. When somewhat cooled and dry, give all it wants, then feed the grain. In summer pump a large trough full an hour before the horses come from the field; let them drink about three gallons each, then wait a moment, and afterwards permit them take all they want.

Salt once a week is often enough on dry feed. When in pasture, it should be placed where the horses can obtain it as desired. Provide plenty of bedding, and see that it is dry. Shake it up the last thing at night, and remove all that is wet or soiled. Straw, forest leaves, sawdust, or any material that is dry and absorbent, is good. Use the currycomb and brush, whether the animal is dirty or not. Go over the animal from head to foot, once a day at least. Be very careful not to scratch or hurt it in the least. Good horses are often made vicious by rough currying. If it is thin haired and tender, use a stiff bristle or wire brush, instead of a currycomb. Wash off the dirt that is difficult to remove, then rub dry with a cloth and brush. Comb out the mane and tail, and keep them smooth. There is much pride in a horse, and it should be promoted rather than restrained.

Harness a horse gently; keep the collar clean and have it fit. Adjust the harness so that no part hangs loose, or chafes. Do not check tight, or use blinders. Fly-nets for horses are invaluable in fly time. A horse will always do its utmost willingly for a kind master. Do not worry the life of a fast, high-spirited horse, by working it with a slow one. After a day's work in summer, turn it into a yard to roll and straighten the limbs. Never let a horse stand out of doors unblanketed after driving in cold weather. Do not worry a horse when driving by continually clucking or talking to him. Teach the animal to start and stop by voice, and to obey a light movement of the reins. A horse may be taught a great deal by an intelligent driver, but the words of command should be few and distinctly pronounced.

BREEDING.—Raise good colts, they cost no more to feed and care for than scrubs, and bring over twice as much in the market. The sire should be absolutely sound in wind and limb, and the dam, well shaped, and of good size. Light work will do her no harm; heavy work will. The average period of gestation is three hundred and forty seven days. Keep the dam in a well-bedded loose box, a week or ten days previous to foaling, and feed hay, carrots, bran, potatoes, and very little, if any grain. Do not work her until the colt is at least six weeks old, then keep it in the stable during the day, and let both run in the pasture at night. As soon as the colt shows a disposition to eat, give it some oats and bran, mixed with a little shelled corn and chopped carrots. Provide it with plenty of water during the day. After weaning, treat it like a horse; halter, curry, and handle, in the same manner. Feed it the best you have, and keep its coat smooth, and in good condition, by all means. When two years old, harness, and drive to a light wagon. Trained colts never require breaking, and they are worth from ten to twenty-five per cent more than wild, unbroken colts, simply because their action is already developed under harness, and they may be termed a finished product.

DISEASES, INJURIES, ETC.—Farmers are not supposed to be veterinary surgeons, and it is rarely advisable for them to attempt to doctor stock, when they do not understand the nature of the ailment; for they are almost certain to do more harm than good. Whenever stock is affected by any disease that is not understood, it is best to refer the matter to a skilled veterinary surgeon at once. There are a few ailments any farmer can attend to; the most

common is colic. Feed and water as advised, and colic will be almost unknown. A pint of oil, with one ounce of sweet spirits of nitre, is an excellent remedy. Injections of warm water or soapsuds, and walking about, will frequently cure in a short time. For Scratches, keep the legs clean, and the bedding and stall dry. Should a long spell of wet weather induce this trouble, get olive oil, eight ounces; liquor subacetate of lead, four ounces; carbolic acid, two drams; mix, and apply with a sponge, once a day. Keep the legs and feet perfectly clean and dry until cured. Feed lightly, carrots, bran mash, etc. Lameness is caused chiefly by hard food, like corn on the cob. Soft food cures it. The man who burns it out with a hot iron, should have his toothache cured in the same manner. To prevent galled shoulders, use a perfect fitting collar. In case the skin on the shoulders is thin and liable to break easily, use a light, wool-faced collar, or a sweat-collar, and bathe the shoulders with strongly-salted cold water, noon and night. If the skin is abraded, apply a lotion, made as follows: Sugar of lead, one ounce; sulphate of zinc, two ounces; rain water, one quart. Give rest until entirely cured. If a horse has been accidentally exposed and taken cold, lost his appetite, is stiff, and has a staring coat, blanket, and put him in a warm, well-bedded loose box. Give tepid water to drink, and feed with a mixture of bran and oats wetted. Once a day, mix with his feed, two drams powdered gentian root, one dram ginger, three drams saltpetre. This mixture is superior to any "condition powder," and is excellent for horses out of condition.

A House for \$100.

CYRIL MARR, SELMA, CAL.

It often occurs in these days of preemption and homestead rights, that a person having a very limited capital, wishes to construct a dwelling with the least possible outlay. To do this requires not a little tact, as well as a fair share of mechanical knowledge. The writer has constructed and lived in such a house for several months. Though small, it afforded fair accommodations for five persons, three adults and two children. The size of the entire structure was twelve by eighteen feet, with walls 12 feet high. Figure 1 shows the exterior of the house. Figure 2 gives the lower story, consisting of a sitting-room nine and one-half by twelve feet, and a kitchen six and one-half by twelve feet. This allows two feet for stairway,

Fig. 1.—EXTERIOR OF HOUSE.

with eight feet between floors, and stairs built as shown. There is room for a passage between the sitting-room and kitchen at one end, and for a closet at the other. Figure 3 shows a bedroom, nine and one-half by twelve feet, and another eight and one-half by twelve feet. This last, when not needed for a bedroom, can be used as a store-room. This upper story is lighted by a half-window in each end of the house.

The Estimate for Material is as follows:

3 pieces, 2 by 4 in., 18 feet long, for sills for foundation.
9 pieces, 2 by 4 in., 12 feet long, for floor joists.
26 pieces, 1 by 6 in., 18 feet long, for floor.
36 pieces, 1 by 12 in., 12 feet long, for two long walls.
8 pieces, 1 by 12 in., 14 feet long, for ends.
8 pieces, 1 by 12 in., 16 feet long, for ends.
8 pieces, 1 by 12 in., 18 feet long, for ends.
36 pieces, 1 by 4 in., 12 feet long, for battens for long walls.
8 pieces, 1 by 4 in., 14 feet long, for battens for ends.
8 pieces, 1 by 4 in., 16 feet long, for battens for ends.
8 pieces, 1 by 4 in., 18 feet long, for battens for ends.
2 pieces, 2 by 4 in., 18 feet long, for upper end plates.
2 pieces, 2 by 4 in., 12 feet long, for upper end plates.

2 pieces, 2 by 4 in., 18 feet long, for plates for upper floor.
9 pieces, 2 by 4 in., 12 feet long, for joists for upper floor.
26 pieces, 1 by 6 in., 18 feet long, for upper floor.
7 pieces, 2 by 4 in., 18 feet long, for rafters.
20 pieces, 1 by 4 in., 12 feet long, for sheathing.
10 pieces, 1 by 4 in., 14 feet long, for sheathing.
4 pieces, 1 by 12 in., 14 feet long, for partition above & below
4 pieces, 1 by 12 in., 16 feet long, for partition above & below
4 pieces, 1 by 12 in., 18 feet long, for partition above & below
9 pieces, 1 by 12 in., 12 feet long, for side wall of stairs.
2 pieces, 1 by 12 in., 12 feet long, for stiles for stairs.
2 pieces, 1 by 12 in., 12 feet long, for steps for stairs.
2 pieces, 1 by 4 in., 18 feet long, for scrub-board.
4 pieces, 1 by 4 in., 12 feet long, for scrub-board.
Assorted 12 feet for door and window casing.
Assorted 36 feet for foundation.
The lumber at the ruling prices here would now cost. \$65.00
Shakes (split boards)..... 7.50
1 door, \$1.60; 2 windows, @ \$2.00, \$4.00; 1 window, \$2.75. 8.35
1 lock and 1 pair hinges, \$0.65; nails, \$1.50..... 5.15
Lining cloth, \$2.50; lining tacks, \$0.50; wall paper, \$1.00. 4.00
Total..... \$90.00

The ten dollars short of the amount mentioned, will allow for any minor changes that may make

Fig. 2.—FIRST FLOOR.

Fig. 3.—UPPER FLOOR.

the plan conform to the desires of the builder; or, in the event of extra hire or freight-bills, this amount will be sufficient. The plan and estimate here given presumes that the owner does his own work. There is no particular skill required. Even these figures may be cut down, as old lumber can sometimes be procured for foundation and braces. Sheathing should project six inches at the ends of the building. Strips, one by four, nailed between pieces of sheathing and lengthwise, if rafters, will make the upper story tight enough for comfort.

A Money-Crop for Next Spring.

In the spring every one wants greens of some kind, and they meet with a ready sale. By far the best and most profitable crop of this kind is spinach. It is easily raised, and farmers who supply the markets will find it very convenient to have a crop that will bring ready money early in the season. To have a crop of spinach next spring, we must begin now. The seed is not to be sown until next month, but the preparation of the soil may be made this month. No matter how highly manured the land may have been for the previous crop, it can hardly be too rich for spinach, and a liberal dressing of manure well worked into the soil will pay. The soil should be brought into a fine condition, by thorough plowing, harrowing, and rolling, and be ready for sowing next month. If to be treated as a farm crop, mark out the rows at distances suited to the narrowest width of the cultivator, say twenty-one to twenty-four inches apart, and sow an abundance of seed. Set the drill to drop the seeds half an inch apart or less. Some cultivators prefer to sow by hand. What is of special importance in sowing spinach, especially at this season, is to bring the soil in close contact with the seeds. This may be done by the use of a moderately heavy roller, or by going over the rows and pressing the soil firmly upon the seed with the feet. Attention to this, especially in a dry season, may make all the difference between a good stand and a poor one. The time for sowing in the climate of New York City, is from the first to the fifteenth of September; in cooler climates the first named date is preferable. When the plants are up, the spaces between the rows must be kept well cultivated, and the plants thinned to two or three inches in the row. This will leave the plants twice as thick as they should be, and a final thinning to five or six inches should be made. The plants at this thinning should be carefully cut out with a knife or with a sharp, three-cornered hoe, and the thinnings used or marketed. At the approach of winter, in all severe localities, it is well to give the spinach a light covering of straw or other litter, to prevent injury from hard freezing. There is no difference in the hardness between the kinds catalogued as "winter" and "summer" spinach.

Australian Wool Farming.

The great staple of Australia, fertile as the island continent is in most natural and cultivated productions, is wool. Except where it is actually a desert, the country offers the best grazing for sheep in the world. Open pastures and park-like woods shadowing a perennially rich greensward, extend in vast stretches over a land whose only drawback is scantiness of water. But where the crops of the soil will not flourish, those on the soil will. The millions of acres which the farmer cannot make productive, bring wealth to the grazier.

Previous to the gold discoveries, thirty odd years ago, Australia was essentially a pastoral country, and since the gold fever has become a thing of the past the farmer has supplanted the miner again. Some of the greatest of the vast fortunes won by wool growing, originated in the mining excitement. Farmers and graziers abandoned their farms to look for swift wealth in the diggings, and wise men bought them in and thus laid the foundations of permanent prosperity. The writer met one sheep king in Queensland, who, in 1852, was a laborer on a farm. The owner caught the gold fever, and his hired man bought him out with his savings. As one farmer after another in the district succumbed to the craze, the long-headed laborer borrowed and scraped together money enough to purchase their estates at the low prices to which all property but mining claims had fallen. To-day he owns an estate larger than some European principalities, and counts his wealth by millions. One of his foremen is a son of his old employer.

Australian shepherds lead a life nearly as patriarchal as a Tartar's. A wild and lonely existence is theirs, and only men of iron physique could undergo it. Two shepherds always chum together, one acting as hut-keeper, while the other is out upon the range. They travel from range to range as the grazing grows poor, and the country is dotted with the rude slab huts they find shelter in. Their fare is of the rudest, consisting of "damper," a sort of bread made of flour and water, baked in the wood embers, mutton and tea. Of late years the luxury of canned meats occasionally falls to their share. Tobacco is their only luxury, and a battle with the fleas which infest their huts, their only rest. It is not so surprising

THE "WOOL-WORM."

that such men celebrate a visit to town with a debauch, and like our own cow-boys, sometimes become a terror to the peaceful townsmen.

The Australian wool-grower's greatest enemies are the catarrh, the scab, the foot-rot, which is caused by marshy grazing grounds, bad servants who neglect the flocks, and the wild dogs. The latter were once a formidable foe indeed, but their destructive hordes have been greatly decimated by the hunters, who shot them by thousands, to obtain the bounty offered for their scalps. These dogs will hunt a flock of sheep as systematically as men

conduct a drive of deer. They surround and close in on them, rending and devouring all in their path. Great flocks are often stampeded by them, when the sheep run until they drop exhausted, or struggle into some stream and are drowned.

The shepherd's dog is as sagacious and true a friend to his woolly charges as the wild dog is a relentless foe. Sheep raising has produced in Australia a peculiar breed of dogs, different in

AN AUSTRALIAN SHEPHERD.

many appearances from the European shepherd dog, but akin to it in all good qualities. These dogs seem to know all the sheep in a flock. They will hunt for stragglers miles away from the hut, and either drive them in or watch them, if they happen to be exhausted, until they gather sufficient strength to walk. It is a common thing in traversing the grazing country, to come upon one of these noble brutes on guard over a strayed or broken down sheep, and woe betide the stranger who attempts to lay hands on his helpless protegee.

In addition to the wool crop, the Australians derive a huge revenue from the boiling down of sheep. Boiling down was originally resorted to on the occasion of a panic forty years ago, when sheep could not be sold in the local market. Then the surplus of the herds was reduced to tallow, and a market for that commodity opened in England. Some years after, huge canneries for the preservation of the mutton were started with satisfactory results. Now the sheep grower makes capital out of the flesh and fat of his flocks, as well as their wool. Another extensive trade is the preparation by salting and smoking of mutton hams, which are used for ship's food throughout the Indian seas.

The busy time on the Australian ranges is in the shearing season. As that time comes around, the wool tramps put in their appearance, tramping over the plains towards the different sheep stations. The wool tramp is one of those nomads like our harvest tramps in the West, whose labor is very useful when it comes in the right time, and who at all other periods are utterly useless beings to themselves and all the world.

A sheep station is the centre or headquarters of a range. Here the proprietor lives, surrounded by his overseers and storekeepers. In addition to the proprietor's and his subordinates' houses, the station consists of a few shops, some barracks for the shepherds, and paddocks, covering hundreds of acres, all fenced and posted as stoutly as can be. The largest buildings at a station are the shearing and sorting sheds, and all important stations now appear to have huge steam presses for bailing the wool. At the smaller stations the hand-press is used. Small sheep-owners drive their herds in to the large stations and there sell the wool.

This disposition of the wool-clip, has given existence to a character in the shape of the buyer of wool, who is known among the small grow-

ers as the "wool-worm." The wool-worm will buy a clip while it is yet on the flock, and the improvident sheepmen take advantage of this and pay usurious interest for the accommodation. These wool buyers have the country districted. One never trenches on the other's ground, and one and all are said to be willing to advance money on the clips several years ahead. The result is that many flocks are under perpetual mortgages, and in the end fall into the hands of the usurers, who sell them at once, for they find much more profit in buying wool than in raising it.

As the shearing season comes around, the flocks are driven to the stations where they belong. Watering carts keep the dust laid, as day after day the woolly legions come marching into the paddocks. If the weather is rainy, they are sheltered in the large "sweating sheds," into which from two thousand to three thousand sheep can be packed at a time. When the campaign is ready to open, the "yarders" are mustered to duty, which is to keep the shearers supplied with subjects. Then the animals pour into the shearing sheds in a steady stream. They are kept in pens there until sheared, and then turned loose to be marked and penned until they are driven out on the ranges again.

The fleece having been clipped, is passed to the wool tables, where it is sorted and "skirted," or cleaned of the rough dirt which adheres to it. Australian wool is divided into first, second, and third qualities, before it goes to the press.

The laborers at the station work day and night in shearing time. From the proprietor and manager, down to the wool tramp, they enjoy only the briefest rest. The wool having been pressed, the bales are weighed and marked with the distinguishing marks of the station. The transportation to market, or the nearest railroad station, takes place in huge platform wagons, drawn by six or eight horses or oxen. These wagons carry from thirty to forty bales to a load.

The station fills up with peddlers of all sorts of wares, not forgetting the "sly grogsmen," who is the master of a bar-room on wheels. Between these and the regular shop-keepers, most of the money made by the laborers at the shearing, is gotten rid of before they leave. The shearing over, the clipped flocks straggle out to the ranges again, the wool tramp takes up his stick and departs, the proprietor makes his annual trip to the nearest seaport to settle business with his agent,

A PROPRIETOR.

and the station goes to sleep again. The lives of the sheep kings of Australia are not subject to the privations to which the shepherds are exposed of course, but they have also many uneasinesses and discomforts attached to them. Existence at the stations is lonely and monotonous in itself, and the fare, however abundant, by no means varied or elegant. Few of the sheep kings live as well as the American farmer, not because they cannot afford to, but because all their money cannot buy a luxury or comfort which does not exist. Their flocks and their wool-clip form the topics which engross them.

AMONG THE AUSTRALIAN MERINOES.

Drawn and Engraved for the American Agriculturist.

Among the Farmers.

New Series.—No. 4.

COL. MASON C. WELD.

How to be of Real Use to One's Neighbors.

Farmers are to be depended upon, take them all together, to be conservative to the detriment of their own interests, even when special effort is made to demonstrate to them in a *quasi*-benevolent way, in what course their real interest lies. The only way the agriculture of any long-settled section is radically changed, is by individuals coming in, and beating the old farmers at their own trade, raising better crops, better stock, making better butter and cheese, beef and pork, and of course making more money. A man if he really wants to benefit his neighbors, makes a great mistake if he undertakes to enlighten them, to show or explain his methods, theories, etc. No, he must make a mystery of it, telling them that they cannot do the same; that this and that are his secrets; that they must find out for themselves, etc. They must be absolutely driven off their own ground before they will change. This is actually occurring in all the oldest and longest settled sections, by the incoming of foreigners. The young men have deserted the old farms, and all around thrifty foreigners are getting possession of them. The Irish—quick, smart, practical fellows—get together a little money, buy an old place for a little cash, and give a mortgage. Things may look like distress, but wife, and boys, and girls, all work in the field as well as in-doors, and there is money enough to meet the interest on the mortgage, to keep the family in decent clothes, with a liberal remainder for the church.

The German, when he buys, improves things very fast; everything is neat about his place; his living expenses are not half those of an American family, and yet he lives better. He has more pleasure in his food and in his amusements, and more enjoyment with his family, and, as a rule, does more reading. He begins with a poor little farm, but is ever improving. He goes out to day's work, while his wife runs the farm. If there is any teaming, plowing, digging of cellars, and that sort of work, he finds time to do it, and so he turns an honest penny wherever he can. He knows that manure goes twice as far, aye, ten times as far in a liquid, as in a solid state, so his garden, and cabbage patch, and tomatoes, and all those half garden crops, are watered with manure water. Thus a little manure goes a great way, and he beats the whole neighborhood with his "truck," which pays him three or four times as much as any crops the native American farmers about him raise.

Gradually they get into doing similar things on a small scale, then on a larger, and finally trucking and small fruits, and special crops of one kind and another, are, so to speak, all the rage. Meanwhile, the German has become a rich man, and if he does not fall into that besetting sin of thrifty foreigners—tavern-keeping, or liquor-selling on a small or large scale—he will become a prominent and influential member of society. Scandinavians, Scotch, and Welsh, effect the communities into which they come, in very similar, but distinct ways. As a rule, I can learn more from Germans and Scotchmen, than any other class of foreign farmers. It is in raising truck-crops that the Germans excel, and it is in live-stock and fodder-crops, that the Scotch and English farmers are superior.

The desire to make money is such an absorbing one among the middle class of Great Britain, that both Scotch and Welsh are apt to be too sharp, or smart for their own good, and this works disadvantageously to them in many cases; for communities soon learn to put themselves on their guard. There seems to be less of this sort of thing among the English, German and Swedish farmers.

After all, no new-comer can influence an American community in the Northern and Middle States like a progressive American, but as I have already intimated, he must not set himself up as an instructor, or he might as well teach mules. He will have a great deal to contend with. In a real old-fogy district, bad roads, poor schools, and either

puritanism of a cast-iron stamp, or loose morals prevail, and in many sections, both—society being divided between the "Unco Gude," and those of ultra liberal tendencies, in morals and politics.

Calves—For the Dairy or for the Shambles.

I went through, as they say, a lot of veal-calves the other day, they were tolerably fat, a uniform lot about six to eight weeks old, nearly half heifers. It struck me I would see what they promised to make if they could become cows, and I was surprised at the number of unusually promising ones. There were no Dutch heifers (Holsteins), or half-breeds among them. There were many Shorthorns and Jerseys, a few evidently of Ayrshire blood, and of course a good many—fully one-half—of no obvious breed, (natives). Not long before I had been at one of Kellogg's sales, and I verily believe that I could have picked out from these calves, which were all veal before the next day, those which would have proved better milkers, if not better butter makers, than nine-tenths of those sold at one hundred to five hundred dollars each. The farmer who does not know enough not to kill or sell to the butcher, a calf that will make a twenty-quart cow, needs to take lessons of somebody in the a-b-c of his business. Such a man has probably several cows in his herd, which never give over ten or twelve quarts of milk, and very likely poor milk at that.

How to Recognize a Twenty-Quart Cow

when she is only six weeks old, is hard to tell, and yet I think not so very difficult to do. I do not know that I can tell how. I like a thrifty calf, with a good sized head, which is narrow and long, broad in the muzzle and between the eyes, and narrow between the horns. I do not care if the limbs are "strong," as they say in Jersey, and perhaps coarse, but they must be straight; and the tail may be even quite coarse at its setting—this indicates constitution. Then, from the withers to the hips there should be a straight upward slope, so marked that if you see the front half of the calf, you will think she is a small one, while if you see only the hind quarters and loin, you will think her very large. In fact, in point of symmetry, the front and hind quarters ought not to match, and the latter should be by far the larger. I prefer long-bodied, open ribbed, flat-sided, deep-bodied calves. The skin should be loose and flexible all over the body, so that one can grasp a handful almost anywhere. The coat must either be long and silky, a little rough perhaps, but not harsh, or it should be soft and furry. With all this, you should find the teats of good size, well spread, and all the skin about them, before and behind—that which will cover the udder—loose, soft, and elastic, showing, as the Scotch say, "plenty of leather." Such a calf will make a good milker if she is bred at a year to fifteen months old, and after her first calf goes farrow (but not long dry), for a year, or nearly that time, to give her a chance to grow. I say nothing about the escutcheon, because I do not know very much about it, and do not believe in half that is said and written about it. Still I must say I would prefer a good broad, well-winged escutcheon, of the Flandrine type, for if the escutcheon shows anything, it indicates staying power, which is perhaps the greatest merit a cow can have. Many a twelve or fourteen-quart cow will beat a twenty-quart one in the long run, especially in her butter record, the true test of a cow's value.

The amount of butter that a cow will give is indicated by no tell-tale marks that I know of. That must be judged by the pedigree and dam's record, if a calf, or by the scales. The unctuous feel of the hide, its pliability, the abundance of yolk, (the yellow, soapy oil at the roots of the hair inside the ear and in the "butter hall" in the end of the tail) indicate health, and perhaps a tendency to fat secretion, either as butter or fat. But some of the poorest butter yielders I have ever known, showed the most of these qualities, and some of the best had very little to boast of, just enough of oil in the skin to indicate good health, and that the skin was performing all its important functions well.

Color in the skin indicates color in the butter. I have never seen a yellow-skinned cow, that gave pale butter, or a very rich-colored skin in a cow, that did not give yellow or yellowish butter all through the winter. When the yolk, which gives this color in the ears, tail, and skin, begins to show in a calf, it will probably never show less, and what butter the cow gives will be of good color.

The New Dairy Law of New York.

I have heard much discussion among farmers in regard to the working of the New Dairy Law. Some holding it to be impracticable of execution, others heartily approving of it. The Law seems to me to be a fairly complete one, albeit somewhat cumbersome, and leaving too much to the interpretation and decision of the Commissioner. It defines clearly what shall be considered as pure and wholesome milk, stating the quantity of solids, including fat, which must be contained in the milk at not less than twelve per cent, while the amount of fat must not be less than three per cent. Besides it declares that milk produced by cows fifteen days before, and five days after calving, or by cows fed upon food in a state of fermentation or putrefaction, "or upon any unhealthy food whatever," to be unwholesome and impure, without reference to its analysis. Ensilage from silos, is made a special exception among fermented foods. Thus it would seem, that the use of brewers' grains, starch feed, glucose feed, and such like articles of feed is pointedly forbidden for the production of milk for sale, or for delivery to creameries or cheese dairies.

Many farmers have felt regret in being obliged to use the articles, because otherwise they could not compete in the production of milk with those who did, even though they knew well that the milk produced was inferior, if not unhealthy. These, and they are our best milk producers, rejoice at the law. Some have cancelled their contracts for grains, on the ground that they are prohibited using them by law. Others will not pit the grains as usual, for fear that they will thus render themselves especially amenable to the law. Others use the grains and pit them as usual. This system of pitting consists in buying brewers' grains in large quantities, when they are very low, and filling pits, like cisterns, with them, well tramped down and covered as nearly air-tight as possible. The grains will keep for months without rotting. They become very sour, and yet are eaten with avidity by cows. The milk produced by these grains, whether sour or fresh, is watery, and lacks richness and good flavor. This sourness is the direct result of fermentation, and increases with age. Access of air, or exposure of the mass to the air, causes rapid decay. The substances pass from fermentation to putrefaction with astonishing rapidity. The brewers' grains come warm from the "mash," and never cool; before the heat of the mash-tub is gone, that of fermentation begins. They are partly cooled off when loaded into railroad cars, but soon heat again. If they are two or three days on the cars—say shipped Friday, arrive Saturday, and cannot be unloaded until Monday, the whole surface to the depth of three to six inches will be gray with mould, black in spots from decay, and the interior as hot as a person can bear his hand in. The sweet smell of fresh grains is rapidly lost, and the sour, unhealthy mess which is left, is utterly unfit for milch cows. The law wisely discriminates against such food, and if carried out will force the drying of these articles, if to be fed, or their use as manure.

REMOVING STUMPS.—There are numerous methods of removing stumps, and there are many cases when it is best to use none of them. It will frequently cost more to rid a field of stumps than the land is worth after the stumps are removed. The use of a chemical to induce decay, or salt-petre to make them burn, is unprofitable, and any method of so-called electricity is mere clap-trap, and money spent in driving nails and fixing up wires is thrown away. Boring the stumps or making a hole beneath them, and blasting them with dynamite, or giant powder, is the quickest method, but one needs to count the cost before engaging in this work.

Walks and Talks on the Farm.

New Series.—No. 2.

JOSEPH HARRIS, M. S.

"Did you see that article in the papers about eighty-cent wheat?" asked the Deacon, as he sat in the shade of a maple tree in the corner of his clover field. "It looks as though this country was going to see hard times. We can make nothing in growing wheat at present prices, and I do not see how the farmers at the West can either."—"Well, Deacon," I said, "you and I have lived long enough to know that dark forebodings of evil are usually exaggerated. I have seen good wheat sold for 'three York shillings' a bushel, and I believe you once sold some for twenty-five cents a bushel. Look round, Deacon, and see what has been done since you first bought this farm. Where we now sit, and for miles around, nothing but forest. The first time I came from Rochester, in several places along the road, so-called, I had to crawl on the fence to keep out of the mud. Now we have a really good gravel road. We have churches, school houses, substantial homes, fine orchards, good gardens, handsome lawns, with bright, intelligent, well-dressed children playing croquet, etc. Do not interrupt me, I know what you would say. These changes, whatever evils may come with them, are for the better. Forgetting the things that are behind, let us press forward. Courage, hope, self-denial and work, have hitherto sustained us, and depend upon it, the world will not come to an end till the end comes—even though we have 'eighty-cent wheat.' But we shall not have eighty-cent wheat—at any rate, not for long. It cannot be. Writers on this subject overlook one fact. They say a man has but one stomach, and that not a large one. It is soon filled, and no matter how cheap wheat may be, he can not eat more than he can. Improved implements, they say, and cheap transportation, and the clearing up of new lands, and the use of fertilizers on the old farm, have so increased the production of wheat, that there is an actual surplus which the world cannot use. There are not stomachs enough. How short-sighted this is. It is true that a man cannot eat more than a certain amount of bread. It is also true that he can do more work in a given time than at any former period. People are better educated. They have the best of tools, implements, and machinery."

"Yes," said the Deacon, "and on the cheap, new lands of the West, they can produce wheat and send it here at a price that will ruin us."

"Wait a moment, Deacon," I replied, "you think I am wandering from the subject. Perhaps I am, perhaps not. What I am trying to get at is this: The world, as a world, is better educated, more skillful, and possesses wonderful appliances of all kinds, and ought to be, and is able to do a given amount of work in half the time, or quarter the time than it could fifty or twenty-five years ago, and consequently the world is twice as rich, or four times as rich as it was. Now, what will the world do with its surplus wealth? It cannot eat more wheat, you say, it can wear better clothes, and live in better houses, and have more comforts and luxuries, but it cannot eat more bread. And consequently the farmer, with his improved facilities, can very easily overstock the market, and leave himself no profit, and no adequate compensation for his skill and labor."

"There is no truth in this idea. An intelligent man does not want to live on bread alone. We think more, work harder, and want better, more nutritious, and more easily digested food. We want more beef, mutton, lamb, veal, pork, butter, cheese and milk. We are searching the world over for these products of the farm. There is no article of commerce, trade, or manufacture, that is more needed, or is in greater demand than good meat. And the more intelligent, skillful, industrious and wealthy the world becomes, the more meat will it want, I was going to say, need, and I believe it, but will not insist on this point. It is certain, however, that the demand for meat is steadily increasing, and the price advancing. It is a costly article.

Ten pounds of gluten in bread, or legumin in peas and beans, or vegetable albumen in grass, will rarely give us over one pound of fibrine or albumen in beef or mutton. Animals are expensive machines which have to be kept running night and day, and it will require all our skill, experience and science in breeding and feeding, to produce the meat which the world will eat. A densely settled country like China, is necessarily filled with a vegetable-eating, and not a meat-eating people. If India, Russia, Australia, California, and our new lands in the Northwest, furnish the world with cheap bread, the world will have more money to expend in meat, and will be able and willing to pay good prices for it.

"A year ago, the Queen of England, owing to the scarcity and high price of mutton, thought she would do all she could to stop the killing of sheep before they had got their full growth, and ordered that no lamb be eaten in her household. Poor Queen, her intentions were good; but it is not the scarcity of sheep that is the trouble, but the scarcity and cost of food that is required to raise and fatten them. Then why talk about over-production? If grass, hay, corn, oats, barley and wheat are too cheap, sooner or later they will be converted into beef, and mutton, and pork, and the good Queen can have her roast leg of lamb, and mint sauce, without hypotheating the crown jewels."

"Our old friend, the Doctor, once remarked: 'if you want to make money, aim to produce the luxuries, rather than the necessities of life.' The fact is, the so-called luxuries soon become necessities. It is certainly true of meat, eggs, milk and butter. And this reminds me, Deacon," I said, "that instead of cabbages, you had better grow cauliflowers, and still better, celery. Celery is now somewhat of a luxury. It will soon be considered as necessary as any other vegetable. And we shall soon have thousands of acres of our mucky, swamp lands, occupied with the crop, and it will be boxed up and sent all over the world."

"My own plan of growing it involves very little labor. It is planted on land so low and so wet, early in the season, that it cannot be plowed before the middle of June. It is light sand and muck, not naturally rich. At any rate, it produces only a moderate crop of grass or hay. We plow the land as soon as it will work properly, and harrow and roll. Then with a common corn-marker, we mark off rows five feet apart, and scatter along these rows a mixture of half superphosphate, and half nitrate of soda, say a good handful to each yard or two paces of the row. We do not sow it broadcast, but drop it along the row. We then take a horse-hoe or cultivator, remove all but three teeth, and set the cultivator as narrow as possible—say at fifteen to eighteen inches wide, and let the horse walk along the mark, and set the cultivator to run as deep as we can get it to work properly. We sometimes go twice in the row. The object is to make the soil as loose, and deep, and mellow as possible, and to mix the superphosphate and nitrate with the soil. Set out the plants in the rows eight or nine inches apart. You will be astonished at the good effect of the cultivator. It makes the soil so loose that the plants can be set out with the greatest ease. Of course, it would be just as well to cultivate the whole of the land, but this plan saves time, and the land between the rows will be thoroughly cultivated afterwards, in order to keep down the weeds."

"If the land is rich enough, it is not necessary to use the superphosphate and nitrate; but on my farm, I find great advantage from its use on celery, strawberries and asparagus."

"How late will it do to set out the celery plants?" asked the Deacon. "In this section they can be set out as late as the first week in August, and later as you go South."

"Are you going to get a binder?"—"No, not as long as I can hire two. There are enterprising young men in every neighborhood, or ought to be, who will keep one or two or three binders, and go round cutting wheat by the acre, just as they keep steam threshing machines, to thresh grain by the bushel. It is cheaper to hire than to buy."

"I hired two binders last year, and hope to do the same thing this year. All we had to do was to stick up the sheaves in stooks. Harvest time is now about our most leisure season. I thresh in the field where the wheat grew, with a steam thresher. Make the straw-stack in the field, and draw the straw home in the winter."

"But suppose it rains?"—"We stop. If we were drawing to the barn we should have to stop also. And we can draw faster to a machine in the field, than we can to the barn—at any rate we can unload faster, because the man on the load has merely to throw the sheaves on to the platform of the machine, whereas in the barn, or at a stack, towards the top, he has to lift them up above his head."

"Our mowing machines, reapers and binders, and steam threshers, are all that we can desire, with one exception; the straw carrier is not long enough. The manufacturer who will double the length of the longest carrier we now have, will receive the hearty thanks of every man who has ever had to take the straw away from one on the top of a stack. It is only a question of a few pounds more coal. In this section, straw is valuable as fodder for sheep and horses, and we all want good, high stacks, well topped off to shed the rain."

"My sheep all through the winter months get no hay; nothing but straw and malt-sprouts. After lambing, we give the ewes clover hay, and a few mangels, malt-sprouts or roots. I can wintertwice as many sheep as I can summer, and such is the case on most of the farms in the wheat-growing sections. You will say that this means too much grain, and too little grass and clover."

"Meal and water is good for man and beast, easily made, and it is surprising that every farmer does not use it. Oat-meal is better, but for horses, cows and sheep, we use corn-meal. All we do is to stir in some meal in the water in the trough where the horses drink. If it gets sour, empty the trough and let the pigs have it. At first the horses do not like it, and it is better to give them a little in a pail, until they get used to it, when they will drink it as readily as pure water. When the horses come home tired and thirsty, at noon or night, nothing can be better for them. Or at any time when they have to work longer than usual, a drink of meal and water puts new life and vigor into them. By stirring up the meal from the bottom just before the horse drinks, or even while he is drinking, he will get more meal."

For some time the Deacon had not been listening. This is an old story to him.—"There he is, the villain," he exclaimed, and started for the barn. There has been a crow in the neighborhood, probably an escaped tame one, that carries off eggs and chickens. It makes the Deacon very mad. While I was talking, he caught sight of him, and ran for the gun. I have not heard the report, but sooner or later, I have no doubt the Deacon will get him."

Do Toads do Harm?

Strange as it may appear, all do not recognize a friend in the toad, for we are asked, "if they do any harm in the garden?" Under the writer's front stoop there is a shelter for several toads, and it is great amusement to watch them as they come out towards night for their evening meal. An insect is seen, and then he is not. One can not, at first sight, follow the rapid motion of the tongue of the toad, as it whips up the insect with the rapidity of a wink. The ancient belief that the toad's head contained a "jewel," must have had reference to that tongue of his, which is indeed "a jewel" in the way of an insect destroyer. Harris, the entomologist, states that he fed a toad with some black caterpillars, about three-fourths of an inch long. When he had fed a hundred he was tired, but the toad was not, but was ready for more. Toads are welcomed in our garden, but snakes, which sometimes come in from the woods near by, are not, but only because they prey upon toads. By all means encourage the toads, and discourage the snakes.

The Rival Beef Breeds.

F. D. COBURN, KANSAS.

Considerable changes have occurred within a quite recent period in the popular estimates and selling values of cattle of the various beef breeds, most common in the great grazing territory between the Allegheny and Rocky Mountains. Perhaps the most remarkable of these is the introduction, in comparatively large numbers, of the polled Aberdeen, Angus, and Galloway cattle from Scotland, and their wide dissemination at high prices, mainly to ranchmen on the Western prairies; prices which at the spring sales of the present year have been considerably cut down. The latter fact is partly accounted for by a determination of many cattle raisers to no longer pay two or three times as much for animals of breeders that here, under existing circumstances, are largely experimental, as for others of a breed or breeds of thoroughly demonstrated value under like conditions. This determination is also strengthened and the prices lessened by the pedigree of many of the newly-introduced animals being presented in such shape as to give small assurance of their being better than grades, while some of the individual animals have little more to recommend them than their being black, hornless, and imported. In spite of high prices heretofore, or apparent low prices now, there is no doubt that the best of these black cattle have great merit, upon which, like their competitors, they will be judged, bought and sold.

The Herefords were almost unknown in America a decade ago, when the bare suggestion of their ever being formidable competitors in the beef classes was regarded by ninety-nine persons in a hundred as most ridiculous. They have shown themselves the peers of any, in the stall or on the butcher's block. In price they are held more firmly by their owners than cattle of any other breeds. They occupy this position not from merits assumed, but from desirable qualities thoroughly demonstrated under conditions adverse as well as favorable, and their popularity founded on the basis of merit seems permanently assured.

Shorthorns, the best known, and most fully tested of all improved cattle in America, have, as a breed, for years suffered harm from the distorted views entertained by many persons raising them, who placed pedigree and color above individual excellence, also from the selling to confiding purchasers as representatives of the breed, thousands of the more unworthy specimens to perpetuate their inferiority, that should have been sent to the shambles. There are weeds in every breed, and if used to propagate from, the standard is sure to be lowered sooner or later. Notwithstanding the mistakes of which they have been the victims, the Shorthorn interest is probably now in a more healthy condition than at any time in the past twenty years. Much of this favorable reaction is due to the rivalry and rapid advancement of other breeds towards occupying the fields before supposed to be all its own. The tendency in rearing each of these breeds is constantly toward a higher beef standard, to the economical and profitable attainment of which other considerations, such as color, pedigree, and remote crosses will be rated but secondary. Let us agree upon essentials.

The Cattle for the South.

Some recent experience with Jersey and Devon cattle, seems to indicate that the latter are best for the tide-water sections of the South. Two years ago a thoroughbred Jersey bull was purchased, and put to service on several of the best obtainable native or graded cows. Six fine calves was the result; but these did not make much headway in growth. Before another season, the bull sickened and died, despite all that could be done for him, though he had a good pasture, and was not allowed to run out upon the commons. Since then, four of the calves have also died, from no apparent cause, unless it be on account of the peculiar character of our summer season. The two remaining calves,

though seemingly healthy, are small and delicate. They may survive, but will never attain the sprightliness and usual vigor of the Jerseys, as I have seen them in mountainous districts. The conclusion is that the Jersey is too delicate for this section. It may do in the more elevated regions, where the summers are not so moist and sweltering as they are nearer the ocean. A first class native, or a grade Shorthorn, would be a safer investment.

This preference for the Shorthorn is based on actual, and somewhat extended tests. Several years ago, when I started farming, I found the grade Shorthorn a very good milker, and excellent for beef and labor. The oxen are strong, heavy, and enduring, and the breed, having had long trial here, appears to be entirely hardy, and fully acclimated. On good pasturage, the Devon develops into a superior animal for beef and for labor. It stands as much neglect, even ill-usage, without material deterioration, as any other breed of cattle. And as there are already here many good grade Devons, any one who may desire to establish a nearly pure blood herd, would only have to procure a full blooded male, and purchase the native grades, which would cost him much less. The partiality that many feel for the Jersey, might lead some in this region (Surrey Co., Va.) to invest more in this breed than would be justifiable under the circumstances.

B. W. J.

Sloping Shoulders in Draft Horses.

The student of horse anatomy from the usual text-books and horse-books, will naturally conclude that an upright arm or humerus (the bone designated as *b*, in fig. 1), and an oblique shoulder are incompatible. That this is not so, is clearly shown in the accompanying diagrams. In figure 1 we have an upright humerus, in figure 2 a very oblique one, and yet the slope of the shoulder blades (*a*, *a*, in each diagram), is exactly the same. It has long been held that while a sloping shoulder is very important for a hunter or a trotter, an upright shoulder does very well for a draft-horse. The sloping shoulder is supposed also to promote high action, which is desirable in carriage horses. From recent observations of Mr. James Howard, communicated

Fig. 1.—AN UPRIGHT HUMERUS.

in "Notes on Cart-horses," to the Royal Agricultural Society, it would seem that we have all been poor observers, and pupils of very poor masters, not to have seen how much more the power, style, action and usefulness of any horse, and especially of a draft-horse, depended upon the position of the leg, rather than upon the slope of the shoulder-blade. In figure 1 the weight of the horse is sustained in front, upon an almost perpendicular column of bone, the humerus, at the shoulder joint, being but very little out of the perpendicular, just enough to give the needed elasticity to the limb. The leg is well forward, which position of course causes the weight of the body to be much more evenly distributed between the fore and hind legs, giving greater stability, and greater propelling power. While, were high action desirable in a draft-horse, and they usually possess it, this position of the humerus is far more favorable to it than the position shown in figure 2. In that we see the fore legs inordinately loaded with the weight of the body, and the bones so connected, especially at the shoulder and elbow joints, that a long stretch of the leg as in fast walking, or high knee action,

can not be taken with any ease, if indeed by any possibility; the whole cause being the obliqueness of the humerus or true arm. We have no doubt as to the great desirability of looking well to this point in draft-horses, and wonder that it has never been forcibly presented to us before. So far as we can see, it is of nearly equal advantage to other horses. Their legs are, however, neither adapted to,

Fig. 2.—AN OBLIQUE HUMERUS.

nor called upon to sustain equal proportionate weight, except, perhaps, in the case of hunters, whose legs in leaping must sustain enormous pressure. It is, moreover, the experience of Mr. Howard, that for both draft and saddle horses, the upright humerus is of greater importance than the sloping shoulder blade. It is nevertheless true, that in draft-horses with very sloping shoulders, high withers are most important. Otherwise the collar will not be held well in position, but will bear too heavily against the chest, shoulder points, and perhaps against the lower part of the neck, so as to obstruct the breathing and inconvenience the horse.

Valuable Points in Horse Breeding.

Mr. James Howard, a famous English breeder of horses, has arrived at some important conclusions in the art of breeding. He believes that the external structure, configuration and outward characteristics, including peculiarities of locomotion, are mainly derived from the sire, while the structure of the various internal organs, the temper, habits, and constitution, come from the dam. The purer the blood of the parent, the more certainty there is of its qualities being transmitted to the offspring. This is particularly true, if the greater purity of race or breed is on the side of the sire. A pure-blooded male that has descended from a stock of uniform color, fixes that same color upon his colt. A sire may influence progeny subsequent to that of which he is a parent; that is, his influence is stamped upon the dam. The transmission of diseases of the vital organs, is more certain from the female, while disorders of the external parts, joints, etc., most surely come from the side of the sire. We know of many exceptions—if they are exceptions—to the above points, and give them more as food for thought for horse-breeders and others, than as rules of action.

Hens Picking Feathers.

The pernicious habit of picking feathers occurs generally among hens and chickens that are confined to small yards, or henneries, without any yard. Villagers are often obliged to raise chickens, if they have them, in very narrow quarters. It is much easier to supply grain and vegetable food, than to furnish the animal food which is essential to the production of eggs. If they cannot get it otherwise, they will pick at the feathers of their neighbors. The pin feathers are a very delicious morsel, and chickens are most likely to be plucked at the moulting time. The old hens will draw blood, and when this is tasted the flesh will follow, and we have occasionally known half-grown chickens to be killed and eaten by the hens with which they were confined. The remedy is animal food in some form, and this should be given without delay, as soon as there is any indication of the

vicious habit. If the fowls are turned out where they can get insects, this will meet the want. Skimmed or sour milk, healthy beef-liver, butcher's offal, fish offal, and chandler's greaves, are cheap forms of animal food, generally within reach.

The Snow Plant of Sierra Nevada.

When the overland route to California was by stage coaches, travellers often gave glowing accounts of the natural wonders to be seen, especially in the Sierras. Among these was the Snow Plant, which appeared as if by magic, suddenly thrusting its blood-red spike out of a snow bank. Aside from a little enthusiasm, these travellers' descriptions were not far wrong. Mrs. B. E. Hunter, of Reno, Nevada, has given us an opportunity of examining the plant in the living state, by sending one "just beginning to grow," the development of which we were able to observe. Botanical works state that the plant flowers as "soon as the snow melts away." Mrs. Hunter in suggestions as to the treatment of the specimen after it should arrive, says: "Place it in water as deep or deeper than it was in the ground. . . . If you put ice in the water it will make it thrive better, as it grows up out of a snow bank, and needs to be kept cold." This confirms the travellers' description as to its occurrence in the snow. The engraving gives the whole plant reduced in size; the specimen sent, when full-grown, was a foot in height. It will be observed there are no real leaves, but instead are numerous fleshy scales, which are broad upon the portion of stem below ground, and long and narrow upon the fleshy flower-spike. At the base of each scale, upon a short stalk, is a single flower, which is bell-shaped, lobed at the mouth, and about three-fourths of an inch long. The flowers, the scales, and all visible parts of the plant are of a dark flesh-red, with not a particle of green about it. Having no proper foliage, the Snow Plant is either a parasite, attached to the roots of some other plant, like our Beech-drops, or else it lives upon decaying vegetable matter (a *Saprophyte*).

THE NEVADA SNOW PLANT (*Sarcodes sanguinea*).

The fact that it will flourish at the low temperature of melting ice is striking, but we have an humble plant, our little Chickweed, that does the same. The Snow Plant is found in the Sierra Nevada, at the altitude of four thousand to nine thousand feet, in the forests of Spruce, and the groves of

Sequoia—the "Big-tree" of California. It was first discovered by Fremont, and described by Dr. Torrey in the "Smithsonian Contributions," who gave it the name *Sarcodes* (resembling flesh), *sanguinea* (bloody). The engraving gives at the left a separate entire flower of real size, and below one cut through longitudinally, somewhat magnified.

Notes From the Pines.

A short time ago, a young man from California called on me, who is known as a horticultural writer. He wished to tell me how much help and encouragement he found in the Notes in his early efforts in horticulture on the Pacific side. I shall continue them from time to time, in the hope that there are other young men who may find them helpful and encouraging. It is, after all, the little matters, those that writers upon horticulture do not regard as of sufficient importance to give a place in their books, the minor matters of practice, that are suggested in one's daily work, that are really of service to the novice.

PLANTING THICKLY AT FIRST.

I was looking over, recently, a work on gardening, which advised, in laying out a new place or in remodelling an old one, to plant shrubs and trees thickly for immediate effect, and as they become too much crowded by increasing in size, to thin them out. Is this good advice? Perhaps it is for some. But when I remodelled this place, I had the same idea and planted thickly, with the intention of thinning, and that good intention has not been put into practice. When a tree or shrub has grown up under one's eyes for ten years or more, if he can put the axe to the root, he has more courage than I. I admit that it would be better for those remaining, to remove it, but then this one that has grown into my affections all these years, will be there no more. I have had a few trees removed while I was away from home, and the vacant places daily remind me of the loss. From my own experience I should not advise thick planting, for when the time for the thinning arrives, it will not be done. A tree-planter should be able to imagine the appearance of his work when the trees have attained their full size. Mr. Elias A. Long illustrates the danger of too close planting by means of a diagram which I borrow. The young trees are shown at the time of planting, and do not appear to be at all crowded. The curved dotted lines show the sizes of the trees at the end of a few years.

THE JAPANESE SNOWBALL.

In my rather large collection of shrubs there is none finer, or that has afforded more real pleasure than the Japanese Snowball. Every one knows the old-fashioned Snowball, to be found in all old gardens. This Japanese species (*Viburnum plicatum*), is vastly superior in every respect. My specimen is now about eight feet high, and when loaded with its snow-white clusters in early June, was a grand sight. The habit of the bush, its rich, very dark-green leaves and snow-white clusters all place it in the very front rank of ornamental shrubs. Being somewhat difficult to propagate, it is held at a rather high price in the nurseries, but it is worth all it costs to lovers of fine shrubs.

COAL ASHES FOR WALKS.

I at one time regretted that we could only get good gravel here by bringing it a long distance by rail and at a great expense. Since I have had more experience in the use of coal-ashes for walks, I prefer them to gravel at the same price. When laid down, some soil should be sprinkled upon the surface of the ashes, and they will soon pack and form a path with a permanent, smooth surface, that is delightful to walk upon. We placed all our own ashes upon the side-walk of the road leading to the railroad station and post-office. A factory a mile or more distant was glad to have us cart away all the ashes we would take, and as a result we have a walk that is dry, firm, and at the same time elastic, making a grand neighborhood improvement.

THE KENTUCKY COFFEE TREE.

Looking out from my window upon a fine specimen of the Kentucky Coffee Tree, I thought what a pity it is, that with this and so many other fine native trees, to give variety, people should go on planting just a few kinds, each one selecting the same, so that one place is just like another, so far as the trees can make it so. The Neighborhood Improvement Societies have done much good work. If they could contrive to teach people the merits of our neglected native trees, they would add to their usefulness. The tree in question may be described as a glorified Black Walnut. The leaves are two or three feet long, are much more divided than in the Walnut (twice pinnate, as the botanists say); the foliage is much more graceful,

ILLUSTRATING ERROR OF NOT CONSIDERING FUTURE GROWTH.

and as it plays in the breeze has a lightness that is most pleasing. The flowers are not conspicuous, and the staminate and pistillate are on different trees. The fruit is a large curved pod, which contains several large flattened seeds. The early settlers at the West used these seeds as a substitute for coffee, which gave the tree its common name. When the abundant foliage has fallen, the tree has a peculiar appearance on account of the large size of its naked branches, and the absence of small spray. From this characteristic its botanical name is derived, *Gymnocladus*, meaning naked branch. Being found from Canada, southward, the tree is generally hardy. The reddish wood is fine-grained and durable, which with its rapid growth make the tree valuable in timber plantations. It is propagated from the seed, and grows readily from cuttings of the roots. The *American Agriculturist* has done much to make our native trees better known, and I suppose that the only way is to keep hammering away at them.

THE PINES.

Save the Potatoes.

JOSEPH HARRIS.

The method of applying Paris Green or London Purple to potato vines infested with the Colorado beetles or "potato bugs," is of comparatively little consequence. The important point is to apply it early enough, and often enough, and late enough. Half-way measures do not answer. It is folly to talk about hand-picking. It is fool-hardy to sit still and hope that the bugs will leave of their own accord, or do little damage.

If left alone, or not killed entirely, they will almost certainly ruin your crop. And mark you, the injury done, whether it is to the extent of one-eighth, one-quarter, or one-half the crop, is so much deducted from your profits. The interest on the land, the cost of manures, the labor of plowing, harrowing, rolling, marking, planting seed, cultivating, hoeing, and to a great extent digging the crop, is the same for a good yield as a bad one.

Potatoes will probably be potatoes next spring. It is seldom they are so cheap as they were this spring two years in succession. But whether they are cheap or dear, provided we grow them at all, it is very unwise to let the bugs eat up the vines and our profits at the same time, all for the want of a little energy, and the prompt and repeated application of a little Paris Green or London Purple.

Two years ago, we knew a man who had two fields

of potatoes. One he "greened" in good season, and the other he thought would get along without it. About three weeks afterwards he found that the potatoes where no Paris Green was used were covered with the bugs. He then applied the poison, and at the same time repeated the application on the first field. On the first field he had two hundred bushels per acre, on the other not fifty bushels, and part were so poor that he did not dig them at all. He lost not less than five hundred dollars worth of potatoes for the want of three or four dollars worth of labor and Paris Green.

The Cabbage Fly and its Relatives.

In England, one of the greatest obstacles the cabbage-grower has to contend with is the maggot of the Cabbage Fly, which sometimes destroys whole fields of cabbages. As the insect has already appeared in this country, and has done some damage, our readers are interested in knowing something about it in advance, that they may be prepared to meet it, when it makes its appearance in their crops. The insect is own brother to the destructive Onion Fly, the Beet Fly, and the Seed-corn Maggot, all of which belong to the genus *Anthomyia*, the Cabbage Fly being *A. brassicae*. The maggots, 1 in the engraving, eat numerous holes in the stems and roots of the cabbages, on account of which, especially in wet weather, decay sets in, and the plant perishes. The maggot, when full grown, is about a third of an inch long, is whitish, leg-less, tapering to the head, and blunt at the tail, which has short teeth-like points at the margin. When its growth is complete, the maggot enters the earth, and changes to a reddish-brown pupa, with a few black spots at the head, and short teeth at the tail, seen in the engraving at 2 and 3, natural size and magnified. In two or three weeks the flies come out, and lay eggs for another crop, and successive generations are produced until November, after which time the pupae remain in the ground unhatched until spring. Cabbages, when attacked by the maggot, show by a drooping of their leaves, and by a change in color, that something is wrong. The application of clear lime-water, made as soon as the presence of the maggot is detected, has been found useful. As the maggot enters the ground close to the plant, and goes down but a short distance, it is recommended, to draw the earth from around the root, with the pupae in it, and destroy them by heat or deep burial. But such measures as these can only be practicable in the garden. On a large scale, relief can only be had by a change of crop, occupying the land with beans, grain, or some other crop, upon which the parent fly will not deposit her eggs.

Another species is known as the Root-eating Fly, *A. radicum*, the maggots of which are found in cabbages and turnips in England; these very closely resemble the maggots of the preceding, but are of a more ochre-like color. The perfect fly is shown at 4, magnified, the lines giving the real size; its colors are black and gray. This insect has not yet been noticed in this country, but curiously enough a maggot, which is very destructive to the eggs of the Locust, that plague of the far

THE CABBAGE FLY.

West, was found to be the larva of a fly, so closely resembling this European Root-eating Fly, that Prof. Riley has described it as a variety of this species.

Though our potato crop has already a sufficient number of enemies, there is a possibility that one

more may be introduced. In England the maggot of another species of *Anthomyia*, *A. tuberosa*, feeds upon the potato. The maggot is given at 6 and 7, of its real size and magnified, and the fly at 8 and 9.

Floral Chenille—Spraguea.

Among the interesting plants made known by the early explorers of the Sierra Nevada, is a mem-

THE FLORAL CHENILLE (*Spraguea umbellata*).

ber of the Purslane or Portulaca family. This proved to be very interesting to botanists, and Dr. Torrey, in view of the great services Mr. Isaac Sprague had rendered to botany, by his wonderfully accurate drawings, named the plant *Spraguea*. After some years the seeds of this plant were sent to Europe, and it went into cultivation. The flowers themselves are very small, and have no beauty, but their large and persistent sepals and bracts, crowded together, make a curious inflorescence. These flower clusters, of a peculiar warm gray color, were at once adopted by the French florists as a most useful material with which to finish off the lower portion of a bouquet. From the resemblance of the flower spikes to that kind of trimming, called Chenille, the plant was named by the French florists "Chenille Florale," and became for a time quite the flower fashion in Paris. The plant is a biennial. Its flower stalks, produced the second year, are six inches or more high, surmounted by the peculiar, recurved, densely flowered clusters. The seeds are offered by our leading seedsmen. The engraving represents the plant in bloom, showing its peculiar habit. Our only trial with the plant was in an unusually dry season, and the next year it failed to flower satisfactorily.

Lady-birds and their Larvæ.

It is fortunate that the Lady-birds are generally so prettily colored, and so handsomely spotted. Otherwise they might fare badly at the hands of those who call every insect a bug, and kill it without stopping to ask what it does for a living. Even those who spare them do not generally know that the Lady-birds have a claim to exemption, beyond their good looks; it is a case where "handsome does" goes with "handsome is." It should be generally known, and children ought to be taught that these are among our most useful insects, and rid us of vast numbers of other insects that do us damage. Every one knows the Lady-birds in their perfect state, but they do the most of their beneficial labor, so to speak, in their working clothes, or in the larval state. In this, or the caterpillar condition, they are not very attractive, though highly useful, and it is important that every one should be able to know them in every form they assume.

In the engraving figure 3 represents the general appearance of the larvæ. They are usually lead-colored, and often marked with yellow, red, and other colors. They move about in such a busy manner that one would hardly suppose them to be caterpillars. Like other caterpillars they are great feeders, but unlike most, instead of feeding directly upon our plants, they do it at second hand and eat the insects that eat our plants, and render great service in devouring myriads of plant lice and other small insects. They actually attack the disgusting fat larva of the Potato-bug of Colorado, which few other creatures, whether bird or beast, can stomach. After an active useful life of about three weeks, they take a well earned rest; hanging themselves up by the tail, they become shining black chrysalids as shown in figure 1. In this condition it appears quite unlike the lively larva it was before, or the bright-colored spotted beetle that it will be,

and it is especially important that it should be recognized in this state, as it is exposed to great danger from ignorance of its real character. We knew of a person who ought to have known better who went out to pick bugs from the potatoes in his garden. He came back with a nice collection

LADY-BIRDS, LARVA, CHRYSALIDS AND BEETLES.

of Lady-birds in the chrysalis state, not knowing his friends from his enemies. This is one of the cases in which even a slight knowledge of insects has a cash value. These engravings will enable even the children to know the useful Lady-birds under all their disguises and treat them as friends.

Variation in the Leaves of Trees.

The number of our ornamental trees is largely increased by the fact that individual trees sometimes vary from the usual or normal form of the species. This variation occurs in the branches, which may be pendulous, and produce "weeping trees," or erect and fan-like. The leaves vary greatly, both in their form and colors, and the flowers and fruit may strikingly depart from those proper to the species. The Weeping Beech, the Fern-leaved and Purple Beeches, are three striking

Fig. 1.—ORDINARY LEAF OF SILVER MAPLE.

and valuable ornamental trees, produced by as many different kinds of variation, affecting the branches, and the form and color of the leaves. Some variations are produced from the seed, the young seedling trees showing their peculiarities from the start. Variations of this kind are to some extent continued by seed. When the seeds of the Purple Beech are sown, the nurserymen expect that a large percentage of the seedlings will have purple foliage. Variations are produced in another manner. A branch appears upon a tree of the normal kind, having a different habit of growth, or bearing leaves, flowers, etc., quite unlike those upon the rest of the tree. The term "sport" was long ago applied to variations occurring in this manner; Darwin called them "bud variations." Such forms are propagated by cuttings, layering, grafting, etc. They often differ from the usual form of the tree in the readiness with which they may be propagated, and sometimes as to their hardiness. The variations in the form of the leaves often give to the tree a very different expression from that peculiar to the species, and the foliage, instead of being dense and massive, is light and feathery. Deciduous trees with simple leaves, may be divided into two groups; one with feather-veined, and the other with radiate-veined leaves. In the first, like the beech, the apple and many others, a strong mid-rib runs lengthwise of the leaf, from its base to its tip, and smaller ribs or veins run from the mid-rib to the margin of the leaf, somewhat like the plume upon a feather. In the other group, the radiate-veined, three, five or more equally strong ribs, start from the base of the leaf, and diverge towards the circumference, as in the maples, the buttonwood tree, etc. Such leaves are also called palmately-veined. We may look upon a leaf as a frame-work of ribs or veins; these are woody and firm, and give strength to the leaf. The spaces between these are filled with a soft, green, pulpy material, in which the work of the leaf is carried on. In leaves of the normal form, there is a great difference as to the completeness with which the margin is filled out. Sometimes there is no break in the margin, not even the slight notches so common; such leaves are called entire. The margins of other leaves are variously indented, and this varies from fine notches, to depressions half way or more to the mid-rib, producing that great variety in outline, so noticeable in leaves. These forms of leaves are characteristic of species. Leaves ordinarily entire, or with slight indentations on the margin, may vary by having

unusually deep divisions; such trees are popularly known as cut-leaved. The feather-veined leaves have the divisions run from the margin towards the mid-rib, and when these are deep, the trees are often called "fern-leaved." The unusual indentation or cutting of the margin of radiately-veined leaves, produces a very different set of forms. The native Silver Maple, or White Maple (*Acer dasycarpum*), is one of our most valued trees for shade or for fuel. Among the many thousands of seedlings that have been raised, a number have shown marked variations in their leaves, and several have

Fig. 2.—CRISPED-LEAVED MAPLE.

been multiplied in the nurseries. The engravings, figures 1, 2, 3 and 4, of the leaves of some of the varieties of Silver Maple, will show how widely they differ from the usual form, which is shown in figure 1.

"Summer Pruning" The Grape Vine.

Each shoot, upon a bearing vine, will have near its base, two or three clusters of grapes. If left to itself, the growth will continue beyond these clusters, and the shoot be prolonged for several feet, ceasing only late in the season. Each shoot will have a few bunches, and beyond them a long

Fig. 3.—CUT-LEAVED SILVER MAPLE.

stretch of vine to be removed at the autumn pruning. In the earlier days of grape culture, and before the vine was as well understood as it is at present, it was advised to "Summer-prune." After the vine had expended its energies in producing this long shoot, it was advised to cut it away in summer, just above the fruit, thus causing a severe check to the vine, and resulting in the ruin of many of the best vineyards in Ohio and elsewhere. A little leaf-folding caterpillar taught a

lesson, which Husmann, and other Missouri vineyardists, were wise enough to heed. This caterpillar was found in the unfolding leaves of the shoot. It cut off the tender stem a short distance above the uppermost cluster of flower-buds. The appearance of the caterpillar caused alarm, but when it was found that the fruit upon the shoots which this caterpillar had pruned, was larger and finer than upon the shoots that had escaped, the hint was at once taken, and shortening the shoots by early pinching, was a great step forward in grape culture. If through neglect, or want of knowledge, the shoots have grown far beyond the fruit clusters, do not cut them back, but stop their growth. Pinch out the growing point of every such shoot, and stop its extending in length. The proper treatment of the laterals is, to pinch back each shoot to its lower leaf. Do not remove them altogether, but always leave the lowest leaf.

Should Farmers Grow Celery?

Formerly the cultivation of celery was attended with so much useless labor in the way of making trenches, and then filling them again, that it was supposed to be a crop only suited to the skilled gardener. The method of treating celery is now so greatly simplified, that it requires but little more skill to cultivate it, than must be bestowed upon a crop of cabbages. There is no reason why the table of the farmer should not be provided with all the luxuries that the garden can supply, and if he has not acquired a taste for celery, he will find ready purchasers for his crop. Farmers near cities and villages, are gradually turning their farms into farm-gardens, and raising crops that bring better returns than corn and wheat. Farmers who supply near markets, will do well to try a crop of celery. Mr. Joseph Harris, in his "Walks and Talks" for the present number, gives about all the directions that a beginner needs, save that we would add one point. In setting out the celery plants, be careful that they are placed no deeper in the ground than they were in the seed-bed. No portion of "the heart," or base of the leaf-stalks, should be covered with soil, as it will interfere with the future growth. Another point is, to have the soil packed firmly against the roots. If the one

Fig. 4.—THREE-PARTED SILVER MAPLE.

who plants gives a firm downward pressure with both hands, as a finishing touch, this will accomplish the proper setting. Gardeners usually go over the row, and by pressing upon the soil close to the plant with the feet, give the needed firming. If plants cannot be had nearer home, they can be obtained of the seedsmen in the large cities. Try celery, if only on a small scale, as preparatory to planting more largely another year. The final treatment, etc., will be given at the proper season.

The Fruit Harvest.

Notwithstanding considerable damage by frost in some localities, the crops in places not visited by this disaster, promise to be so large as to make this, on the whole, a season of abundance. Many new orchards, especially of peaches, will yield their first crops this year, and this increased area may make up for local losses. The means taken to improve the quality of the fruit, and to place it on the market in the most attractive form, will show their value more strikingly in a year of plenty than in one of scarcity. As there is always room "higher up," so there is always a sale for fruit of the very first-class. Among the means for improving fruit, we have often advocated thinning. While it is too late to practice this to obtain the best results, it will still pay to go over choice late pears, and possibly select late peaches, and instead of assorting the fruit at picking time, do it on the tree, thus giving that which remains one or two months or more of time in which to benefit by the nourishment that would have gone to the inferior fruit.

After the peach-grower has brought his trees into bearing he is often confronted by an unforeseen difficulty, that of picking his crop. His returns will depend largely upon the manner in which the fruit is picked, and in localities where peach culture is but recently introduced, skilled pickers are not to be had. Pickers cannot be brought from the peach districts, for they are in demand at home. All that the owner of the orchard can do is to engage the most intelligent hands possible, and instruct them to distinguish between the mature and over-ripe fruit. A peach that can be indented by a moderate pressure between the thumb and two fingers, is too ripe to go to market. The peach crate adopted by the Maryland and Delaware growers is made as follows: Two end pieces seven and a half inches wide, fourteen long, and three-quarters thick. The top and bottom are of three-eighths stuff, six and a half inches wide, and twenty-three and a half long. The sides each require four slats, twenty-three and a half inches long and two and a half wide. These are also three-eighths-inch thick.

Early pears and apples often reach market in a poor and mealy condition. This is due to delaying the picking too long. Early pears as a rule should be gathered one or two weeks before they would ripen upon the tree. The ready parting of the stem of the fruit from the branch should be watched for, and as soon as this takes place the picking should not be delayed. Early apples of first-class are never abundant in the market, though early trash may be plenty. The change of color in the skin or in the seeds, as well as the ready parting from the tree, are guides to the time for picking. It will pay with these, as with later kinds, to carefully assort into two qualities and send to market in attractive form. Bushel crates are better than barrels for choice fruit. In gathering both these and early pears, take care that the stems are not broken, as the beauty of the finest fruit is seriously impaired by a lost or mutilated stem.

Grapes of several kinds are colored before they are fit to be eaten, and many are tempted to send

Fig. 2.—BOUNDARY OUT OF SIGHT.

them to market too early. No fruit is so improved by being thoroughly ripened before gathering as the grape, and those who would establish a reputation for quality will heed this. When grapes are completely ripe the stem loses its stiffness, and the cluster hangs directly down from the vine; the stem also usually becomes colored, or loses its green color. Within a few years the manner of sending grapes to market has greatly changed. Not long ago the flat five and ten-pound wooden box was the universal package. At present vast quantities are marketed in baskets, holding ten and

twenty pounds. These are flat, oblong, splint baskets with a handle. The grapes are laid in carefully and covered with cotton cloth, either sewed on or provided with a string run in around the edge in such a manner as to be drawn tight. Another package for grapes that are not to be kept late is a paste-board box with a wooden bottom. Grapes to be packed in boxes should be exposed to the air in shallow trays in a cool and airy fruit room; the object of this is to "cure" or toughen the skin of the fruit, and this process may require a week or more.

Plums, except the common kinds, are very rare in the markets. Those who undertake the labor of saving their fruit from the curculio, find a ready sale for it at high prices. Choice varieties are packed in fancy boxes and small baskets. The great beauty of this fruit depends upon its bloom, and extreme care is required in picking and packing to prevent the removal of this. The common varieties of plums are marketed in boxes and baskets.

The Management of Irregular Grounds.

Those about to lay out new places, or to remodel old ones, should, in making their plans, take into

Fig. 1.—TERRACE ADORNED WITH TREES.

account the natural advantages of the ground, so far as possible. There is no better time than the present, while the trees are still in full leaf, to judge of the natural features of a place, and what changes may be necessary in improving it. A garden upon a hill-side offers opportunities for embellishment, not presented by a level surface. Such a garden may be laid out as a succession of terraces and slopes, each of which presents opportunities for ornamentation. Being highly artificial, they allow the use of steps, from a higher to a lower level. Mr. Elias A. Long, in his "Ornamental Gardening for Americans," soon to be published, gives the following method of treating terraces and slopes, which removes much of their ordinary formal appearance. In figure 1 the regular outlines of the steps are relieved by the trees at the top of the slope, and there may be introduced a line of showy plants, to be seen from below. The slope, instead of being, as usual, an unbroken surface of grass, may have its ordinary blankness relieved by planting here and there some of the many ornamental shrubs, suitable for the purpose.

In laying out grounds, it should be the object of the landscape architect, to make the area he has in hand appear as large as possible. One method of doing this, to open vistas, through which a glimpse may be had of whatever may be beyond, whether of mountain, the sea, or rural life. Another method of making a place appear larger is, by removing all visible boundaries. It frequently happens that the boundary wall may be placed quite out of sight, as in figure 2. Where neighbors agree to dispense with boundary fences, each can enjoy the view of the other's place. If desired to mark the boundary between the two places, it may be done by means of stones, or low posts of dura-

ble wood, set in the ground on the line. On places, where it is desirable to keep the home grounds safe from intrusion by animals at pasture, a sunken fence, like that shown in figure 3, may be often employed. We have in mind a place, in which a ravine was thus converted into a barrier, separating the pasture lands from the grounds about the house in an invisible, but most effective manner.

The Pecan Nut.—Its Cultivation.

Mr. J. C. Wilson, Chattanooga, Tenn., writes us an interesting letter, advocating the culture of the Pecan tree. He regards this as the most valuable of the nut-bearing trees, those in the woods yielding many bushels each of nuts, which always meet with a ready sale at "fancy prices." As the Pecan will grow on almost any soil, even on rocky hills, Mr. Wilson thinks that every farmer should have his nut-orchard or grove, as a source of profit.

The Pecan tree belongs to the same genus as the hickories (*Carya*), and on account of the olive-like form of its nut, is called *C. oliviformis*. Its natural range is in the valleys of the Western rivers, from Northern Illinois to Texas. How generally it

would succeed in the Atlantic States, is yet to be tested. In the Bartram garden, near Philadelphia, is a remarkable specimen, ninety-one feet high; this tree rarely perfected its fruit, though a young one in the same garden frequently did so. Like other hickories, the Pecan is difficult to transplant, and rarely succeeds if the trees are over one or two years old, unless prepared in the nurseries by root-pruning, and several times transplanting. Mr. Wilson prefers planting the nuts in place to setting out young trees, and in his advice to "get fresh seed nuts of a good variety for planting," he recognizes the fact that the nuts from the wild trees vary greatly. Some of the trees in a grove of Pecans, bear nuts twice as large as

the average of those offered for sale, and with very thin shells and sweet kernels. The writer was stationed in Texas one autumn, near a fine forest of Pecans. The servant kept the mess table supplied with nuts of a size and quality we had not before met with. Upon investigating the matter, it was found that the boy watched the ground squirrels, and finding their holes, appropriated the nuts which these provident animals laid up for their winter stores; these, by "natural selection," were the largest and finest possible. Mr. Arthur Bryant says that he never had any success with planting in the fall, and strongly advises to do the work in spring. Nuts for planting must be kept from becoming dry or rancid. Small quantities may be mixed with sand, using at least a quantity equal-

Fig. 3.—A SUNKEN FENCE.

ling the bulk of the nuts, in a box or barrel, keeping them in a cool place. Several bushels may be placed in a heap on the ground, covered with sods or leaves, and then with several inches of earth. Look out for mice and squirrels. The trees, when full-grown, will need to be thirty or forty feet apart, but if the nuts can be spared, it will be well to plant much thicker, and thin the young trees as more space is required. The thinnings will afford poles and small timber, for which there are always numerous uses on a farm. To guard against accidents, it is well to plant two or three nuts near together, and pull up all the seedlings but one,

A Bed-room in Cretonne.

A room fitted up in cretonne, as seen in the engraving, is very pretty, inexpensive, and makes a light and cheerful summer apartment. The prevailing color is pink. Cretonne of a very good quality can be bought for eighteen cents a yard. The pattern here used has a bright ground, which is nearly covered with leaves and pink rose buds. After the walls are kalsomined, which should be of a delicate shade of pink, paste on, as shown, a wide wall-paper border. This adds greatly to the appearance of a plain wall. The lounge is made of a box, six feet long, twenty-three inches wide, and fifteen inches high. Cleats are placed on the inside of the box to hold the lid. A cushion should be fastened under each corner, after which the box is ready to cover. Tack on the plaiting for the bottom just over the top, so that the cushion will cover the edge. For the cushion, cut two strong pieces of

A ROOM FURNISHED IN CRETONNE.

muslin or partly worn ticking the size of the top of the box, and a piece four inches deep, to be sewed between the top and the bottom of the cushion. One side should be left unsewed until the stuffing has been placed in. For the latter, fine straw or worn out comfortables can be used. Cut a piece of the cretonne the size of the top of the cushion, and make a strip six inches deep, and long enough to go once and a half round the cushion, gather this strip, and sew one side to the piece for the top; draw it over the cushion, and run the other edge of the puff to the underside. The pillows can be of any size, but the larger they are, the better. The frame for the little table is a couple of barrel heads and a small pole thirty inches high. Tack the cretonne on loosely enough to allow it to come together in the middle, after which it is drawn down, tied, and finished with a large bow of pink ribbon or a band of the same material. Make a narrow plaiting of cretonne and tack around the top of the table. The lambrequin for the window is a straight piece, finished at the bottom with a deep hem and sewed on the curtain rings. The umbrella case is not merely ornamental, the pockets are made of the cretonne doubled or lined with some heavy muslin, the back being covered pasteboard. Hang it on the wall with small brass rings, sewed at the top, corners, and bottom; tack a small bow of pink ribbon at each corner of the case.

The corner wash-stand is made of a triangular board, rounded on the outer edge, and supported by three stout legs. Tack the cretonne on the top as seen in the design, leaving it loose at the bottom, so that shoes and other articles can be placed behind it. Cover the top with marbled oil-cloth, and make a screen of dotted Swiss over pink cambric, to tack back of the wash-bowl. The little

corner closet which is so convenient for bottles and wash-stand necessities, is made of two ebonized pieces of wood. The curtain is hung with small brass rings on a nail which is fastened at each corner. The book shelf is constructed in the same manner. The frames for the panel pictures are ebonized pine, or they can be gilded if preferred. The diamond-shaped frame is also made of pine, covered with garnet velveteen. It makes a very pretty frame, and when it is hung up high it cannot be easily distinguished from a velvet one.

Hanging Shelves.

Shelves of some kind for holding books, papers, etc., are always useful in the kitchen or sitting room. Shelves fastened to the walls are not as convenient as movable ones. If you paper or whitewash the room they are in the way; to fit the paper neatly about them is quite a job, and only a skilful white-washer can use a brush around bracket shelves without leaving streaks in the wash. A set of hanging shelves can be cheaply and readily made. Take as many pieces of board as you want shelves, of the width and length desired. If there are two windows on one side of the room, not more than

three feet apart, make the shelves long enough to fill the wall space between them. Paint the boards or stain them to imitate walnut or oak, or cover them smoothly with glazed cambric, and tack a row of fringe about the edge. If you wish the shelves more ornamental, make narrow lambrequins to tack to the front of the shelves. These can be made of some dark cloth, with bright flowers cut from cretonne appliqued, fastening on with an embroidery stitch around the cut-out flower. To fasten the shelves together, procure some stout cord of a color to match the stain or covering of the shelves.

Before attaching the cord, cut a piece of board as long as it is desired to have the shelves apart. Place this between the shelves while attaching the cord, and it will hold the shelves just as far apart as desired. The cords supporting the shelves should be strong, and the nail or hook to which the shelves are hung, needs to be stout and firmly driven into the wall. Let us have more hanging shelves.

Notes on Present Styles of Dress.

Simplicity is the rule for walking suits, cloth and velvet dresses to be made perfectly plain, and a straight collar or ruche, with a bar pin as the only finish for the neck, bows and ties at the throat and necklaces being completely abandoned. Ribbons, however, appear in the place of flowers on evening dresses, made up into rosettes, the ends cut into sharp points.—Watches, too, instead of being hung by a chataine, are now tied by a bright ribbon to the seventh or eighth button-hole, from the top, and worn inside the waist. The touch of color is very pretty in a dark costume.—The hair is still worn in a low knot at the nape of neck for the street, but for full dress is wound in a loose, irregular coil on the top of the head, with a crumpled piece or bang in front. School-girls with golden brown locks bind the hair down with bandeaux of narrow black velvet. It is passed over the head four or five times, and tied in a bow behind the left ear. Young girls carry bags of velvet or satin suspended from the arm by silk cords. These hold their handkerchiefs and pocketbooks, or any bit of fancy work. A monogram can be embroidered on them. Long dove-gray or blue gauze veils seem to be the most popular. They are crossed at the

back, and the ends brought around in front, where they are neatly secured by a small lace pin.

A quaint Mother Hubbard apron is crocheted of éru linen thread, in tiny shells, and bordered by a large shell edging. It is trimmed with narrow cardinal satin ribbon, three rows run in across the bottom, one on each side and two through the band. A pocket is put on one side, and tied at the back with broader cardinal ribbon. If a bib is added, it is pinned up with tiny silver or gold pins in some odd design, as are the bibs of all aprons. Narrow black velvet ribbon is worn tight around the throat.—Ear-rings are very small, and many prefer not to wear any, which is perhaps the better way.—Corsage bouquets are prettiest of natural flowers, and are worn high up, on the left side.

Hanging a Broom.

Mr. C. Lederer, Whitesides Co., Ill., sends us a sketch of a plan for hanging a broom, which is convenient, and keeps the brush part from getting

HANGING A BROOM.

out of shape. Two strong nails are driven five inches apart in a perpendicular line, and the handle of the broom is placed between them, in the position shown in the accompanying engraving.

A Convenient Flour and Meal Chest.

Half the house-keepers in town and country use the flour and meal direct from the bag, sack or barrel as is needed, resulting in a considerable loss. The flour is unavoidably sprinkled and dusted over the floor and surrounding articles of furniture. This can be avoided by using a chest or box, that is easily made, and may be placed in one corner of the pantry. A desirable size for the chest, is two and a half feet in height, three and a half feet in length, and fifteen inches wide, made from thoroughly seasoned pine boards, planed upon both sides, closely fitted together and secured with nails and glue. It is divided into two apartments, the larger one, *a*, being used for flour, the one, at *b*, for meal, while near the bottom is a drawer, *c*, in which the rolling pin, flour measure, cup, sifter, spring balances, and other articles may be kept. The chest should be provided with a close-fitting hinged cover, the whole exterior being painted some light color. No paint or oil is used upon the inside. The bottom is raised four

A MEAL CHEST.

inches from the floor by hollowing out the ends and sides, as shown in the above engraving.

THE HANDS—A "hard-handed" farmer or mechanic need not be ashamed of this mark of his calling. His hands may be "hard," but they may be clean. Always use soft and warm water to thor-

oughly wash the hands. Hard water leaves them rough and unpleasant. Let the hands soak for a minute before soaping them. A nail brush is of great aid in keeping the hands in order; one made with unbleached bristles is by far the most durable. This should be used with soap not only on the nails, but all over the hands, especially on the most soiled portions. Common soaps often contain an excess of alkali, which roughens the skin, and of rosin, which leaves the hands sticky. Castile soap is vastly superior, is quite equal to the highly perfumed toilet soaps, and not very expensive. Keep at hand a lump of pumice stone, with which to rub any special stains and any rough places on the palms. Put on and axle-grease can be removed by first oiling the hands, or lard will answer, thoroughly rubbing it in before using soap. If the skin is disposed to chafe, use with the soap a tablespoonful of Indian meal; rub the hands with this thoroughly, and after rinsing apply glycerine mixed with four parts of water, rubbing the hands together until the water evaporates.

A Laundry Cushion.

Any one having washing done out of the house, will find the use of the laundry cushion here illustrated, a convenient method of keeping a list of articles. A full list of the articles likely to be in

A LAUNDRY RECORD CUSHION.

the wash is written with indelible ink on a piece of unbleached linen about six inches long by ten wide. The name of each article is followed by a row of figures from one to ten inclusive. The linen is then sewed to a second piece of the same size and made into a cushion by stuffing with hair or saw-dust. A cord, by which to hang it up, is fastened to the upper corners, and a row of pins is stuck along the edge. The number of any article in the wash is recorded by sticking a pin in a corresponding number opposite the name of the article. If four tablecloths are sent, a pin is stuck in the figure four, and if there are twenty-four napkins in the wash, pins stuck in figures ten, nine, and five, keep a correct count.

MRS. BUSYHAND.

A Word to Parents.

REV. E. P. ROE.

See that your child never leaves any task half done or slovenly finished; and therefore give not too many tasks. Thoroughness is the corner stone of success. There is no place in the world now for smatterers, who know a little and only a little of everything under the sun. There is always an honorable place for those who can do any kind of honest work in the best manner. Show the child, from the experience of others, that little or no progress is made by spasmodic and intermittent effort. The world is now so advanced and competition so keen that genius must ally itself with patient, persistent work, and with the deftness which comes only from continuous practice. The young are prone to dream of what they will do in the future. The history of others proves that they will never do much, unless they are doing their present work thoroughly. They do not realize this, and mere arbitrary assertion of the fact usually

makes but slight impression. Biographies of successful men, whether read from the libraries or furnished from your memory of neighbors, establish the truth in their minds, and such biographies should be freely read by children.

The Buffalo Moth.

Unlike the common Clothes-moth, the destructive Buffalo-moth is not the larva of a proper moth, or miller, but a beetle. The perfect insect is a very pretty beetle, about an eighth of an inch long, black and handsomely marked with scarlet and white. The grub is about three-sixteenths of an inch in length, but on account of its long brownish hairs appears larger. The insect was first noticed in New York State about ten years ago, but has since spread to such an extent that we have inquiries concerning it from every State. Though most destructive to carpets, it attacks woollens of all kinds as well as feathers and furs. It is in the larval or grub state that the insect does its mischief, the perfect insect or beetle regaling itself on garden flowers, especially the Spireas. The grub works under the edges of carpets, often making sad havoc, it sometimes takes shelter in a crack in the floor and working along that cuts the carpet on the line of the crack as completely as if it were done by shears. This habit of working in the cracks suggests the utility of stopping up all crevices before the carpet is laid down. Putty, hard soap, and plaster of Paris have been suggested as materials for filling the cracks, especially those between the base-board and the floor. Those who vacate their houses for several months at a time should be careful to not leave the insect in possession, as the results may be most disastrous. The most effective method of destroying the insect while the carpet remains in place is the use of steam. A wet, folded sheet is laid along the edge of the carpet. Upon this cloth several hot flat-irons are passed. These generate an abundance of steam which penetrates the cracks and destroys the insects. Furs or articles of woollen, not conveniently steamed may be placed in a tight box, or a wash boiler and a small quantity of benzine poured in; if the box or vessel be kept closed, the vapor of the benzine will kill this as well as the common Clothes-moth. This is one of the most destructive of the house-keepers pests. The insect is a native of Europe, and is known to science as *Anthrenus Serophularia*. It is supposed to have been introduced into this country in imported carpets.

Light Work for Mid-Summer.

The months of July and August appear to have been intended for rest by the Author of the seasons. Through the stimulating cold of winter, the fresh, mild breezes of opening spring—even later, when all nature is awake, and we open the doors and windows to catch the sound of birds and insects, and to breathe the odors of buds and blossoms, we can work with a will and feel interested. Even the dreaded "spring cleaning" had its pleasures as we close up the dreary furnaces and stoves and pack away all reminders of the bitter cold. As summer advances, while we are alive to its beauties,

Fig. 1.

we like to sit under the trees, on the piazzas, or lie listlessly in the hammocks. But to most of us rest does not mean idleness; and to be obliged to spend our time for many days with head and hand unem-

ployed, would be misery. "I could be happy on a desert island with my books and work," said a lady some time ago—one who was prominent in society, and actively engaged in charitable work through the winter; but when the time for resting came she had to be busy still in another way. So while it is well to lay down the heavier duties and cares of life for a few weeks, it is a pleasure to have some light work to "take up," and the revived interests in fancy work of late years, gives a wide scope to one's taste and skill. We say revived interests, because embroidery is one of the oldest of ornamental arts, and one in which there has been no ad-

Fig. 2.

vance of late. Knitting too, now in fashion, was one of the favorite occupations of our great grandmothers, and little children in the public schools of that time had stint of "rounds" on their stockings given them as a daily exercise. Home-made edgings and insertings, both knitted and crocheted, are much used now, and it is a pleasure to study out new patterns for them. It is said that good cotton thread is better than linen, although the latter is rather prettier. Hair-pin crocheted edging is very quickly made, and it is pretty and durable. It may also be a foundation for wider and more elaborate edgings. Make a slip loop and pass it over one side of the hair-pin, then turn the pin around, and you will have a loop on each side. Draw up with the hook a loop through the first loop, * take out the hook, turn the hair-pin, and insert the hook in the loop from which it was withdrawn; then make a double crocheted stitch under the left hand loop—repeat from *. Drawn work is very popular and beautiful. Broad insertings are made of it to trim children's dresses, bed linen, toilet sets, etc. We give an illustration of one which may be made of coarse or fine linen. A pretty and inexpensive gift for a lady is a cake-basket cover, made in a square, with fringed sides in this same pattern. Figure 1 shows the way the threads are drawn, and in figure 2 is seen a portion of it finished. A pretty gift for a gentleman is an umbrella case. The foundation is of paste-board. It may be covered with gray linen, or any other plain, durable cloth. Two strips are embroidered and sewed on the front before making up. They may be ornamented according to one's fancy. A monogram or initial is added at the top as seen in figure 3. A very pretty pen-wiper is made to imitate autumn leaves. They are cut out of flannel, red, brown, yellow, like the leaves, veined with silk, and notched on the edges—then grouped together. Another is a carnation pink. The flower is of red flannel, notched and folded like a piuk, attached to a wire stem covered with dark-green cambrie. The leaves, of cambrie, are made on fine wire. This is novel and exceedingly pretty.

ETHEL STONE.

A Lead-Pencil Sharpener.

Cut a piece of cigar-box or other thin wood, five or six inches long, by one wide. Upon both sides glue pieces of sand paper of a medium grade. Sharpen the pencil with a knife, and finish the point upon this implement, giving either a round or a flat end, as desired. When the point becomes dull, it may be repeatedly "touched up" on this sharpener without recourse to a knife, and which is a very desirable matter, without soiling the hands. By striking the sharpener against any object, the particles of lead are readily removed.

BOYS & GIRLS' COLUMNS

An Adventure With Bruin.

A VIRGINIAN.

Walter Wheelbin is a Richmond boy who had never experienced any rural sports until October

dant. The invitation promised too much field-sport and mountain air to be declined, and Walter, one frosty morning, alighted at a little station on the Chesapeake and Ohio Railroad, where George, with horses, was waiting to meet him, and after a ride of a few miles, found himself at the home of his country relatives. In the Gauley River are nu-

tree, standing on it. One afternoon Walter and George set out in a canoe for the purpose of exploring a number of these miniature islands, the first among which being Dead Chestnut. Just as they were leaving, a noise, as of some animal feeding, and a shaking of the bushes, attracted their attention. They both stood in breathless suspense,

TREED BY A HONEY HUNTER.

Drawn and Engraved for the American Agriculturist.

last, when his cousin, George Wheelbin, who lives on the Gauley River, in West Virginia, wrote him a letter in which he kindly insisted that Walter should pay him a few weeks visit, at the same time not omitting to mention that chestnuts, chineapins, persimmons, and wild game were unusually abun-

derous small islands, many of them mainly large rocks, with sometimes sufficient earth to nourish the growth of a few trees and bushes. The one on which the adventure I am about to relate, took place, is known as Dead Chestnut Island, on account of its having a solitary, large, dead chestnut

with their eyes fixed intently upon the shaking chin-capin bushes, when to their horror the huge, black head of some wild beast, suddenly presented itself in full view. For a short time they stood speechless, and then fled for the canoe, shouting, "A bear! A bear!"—"Gone!" ejaculated George,

pointing to the place where they had left the canoe. "Gone! oh! why didn't we pull it higher up?"—"Too cold to swim, and too swift, too!" said Walter, gazing ruefully into the ice-cold current; "and the island's entirely too small on which to pass the time pleasantly, so long as there's a bear on it!"—"Let's climb the old chestnut," said George, and the suggestion was immediately acted upon. "Get far out on the slender limbs, Walt, where the bear couldn't go, if he should take a notion to come up," said George, but the command was wholly unnecessary, for Walter had instinctively crept as far out as was safe and convenient. From their lofty positions they had a good view of their shaggy enemy, as he roamed at will over the island, picking up mouthful after mouthful of blueberries, and occasionally glancing up, with apparent delight at his treed captives.—"I think I see the canoe away down at the bend," said Walter. "I'm afraid we shall have to try swimming, or else remain here all night."—"I could never stem that current; besides we would both freeze to death in that cold water," replied George, his teeth rattling, and his very frame shivering as a cold, frosty breeze came roaring down the river gorge. "But look!" he added quickly. "Look, he's moving toward the tree!"—"Wonder if we couldn't scare him away?" asked Walter, and then began a series of shoos, etc., to all of which the bear paid no attention, and after walking around the tree two or three times, began very leisurely to ascend.—"Let's jump out and try the water!" yelled George.—"That would break every bone in your body," was the encouraging reply.

The great brute, with no apparent effort, moved slowly up the leaning trunk, until he reached the main fork, in which he coolly squatted, and began to inspect, by alternate glances, his very much frightened prisoners. He did not seem inclined to quit the fork, but sat there quietly, every now and then inserting his paw in a hollow limb, and then withdrawing and sucking it greedily.—"Honey," said George, "Honey. That's what's brought him out here. I have heard father say that a bear will go anywhere, or do anything for honey. Look at the bees he's stirring out, and oh, what eyes!"—"Between the bear, the bees, and the cold, we'll die yet," muttered Walter, between his chattering teeth.—"I believe," said George, pointing down the river, "I believe I see a canoe coming this way."—"I believe so myself," replied Walter, glancing from the bear to the canoe, and then from the canoe to the bear.—"Oh, Walt, I think it is Seeth!" exclaimed George, delighted at the prospect of being released. "Oh, yes, I'm sure it's Seeth!"—"Seeth, sure enough!" shouted Walter, clapping his hands, as that individual's features gradually grew into recognition. "It's Seeth, sure's we're living!"—"Hurrah Seeth! Come quick! A bear! A bear!" they both yelled, waving their hats in order to attract his attention.

Seeth was a good-natured negro, who, before the war, had belonged to George's father. He had caught the canoe as it drifted by his cabin, and upon recognizing it as George's, became greatly alarmed lest some accident had happened to him and Walter, and with this gloomy thought uppermost in his mind, began rapidly paddling up the river in search of them. Upon finding them in such a terrible predicament, he pushed hastily to the shore and ran as fast as he was able for his gun and dogs. Although his cabin was at least half a mile away, he was not long in going to it and returning with his rifle, ammunition, and two dogs. Throwing himself into the canoe, and calling in his dogs, he soon reached the island.

"Be careful how you shoot, Seeth," requested George, who recalled a painful instance of his marksmanship of a few months before, when he fired at a crow on the pasture bars and killed a Jersey calf, standing several yards out of range.

The words were scarcely spoken when the roar of the powerfully charged weapon reverberated along the banks of the river without producing any apparent change in the position of the bear.—"Whistled pretty close to my head that time," said Walter, with considerable alarm.—"Moon's in

de ram," exclaimed Seeth, who believed firmly in all superstitions. "Other times shoots as straight as any gun you ever seed. In de ram it shoots at least two feet outen de way."—"Then aim two feet the other side of him," cautioned Walter, who, in his fright, seemed to have little, if any, consideration for the welfare of his cousin, who was on the side designated. In a minute the gun was again loaded and fired, and the great, black creature pitched headlong to the ground with a jarring thud, and was immediately pounced upon by the eager dogs. He was by no means dead when he alighted, and Seeth, in his desire to finish the work he had so clumsily begun, and to assist his friends, the dogs, assaulted him with the butt of his rifle. One blow, and the whole scene changed. The bear, infuriated with pain, immediately turned upon his tormentor, and sent him flying around the island at a very rapid speed.

Around and around the island he flew, scampering over the rocks and through the bushes, with the bear and the dogs close at his heels, occasionally turning to deal a blow with his rifle, which he still managed to hold. "Run! run! Seeth!" shouted the boys, thoroughly alarmed for his safety. "Jump into the canoe and push off." This command was obeyed, but no sooner had he taken up the paddle, than in fell the fighting bear and dogs, nearly on top of the poor negro, who lost no time in extricating himself and resuming his flight around the island's circumference, every now and then muttering something about the lack of space being unfit for such an encounter, and that he would prefer more territory the next time he might be so imprudent as to attack a bear.—"Hurrah, they have got him now! stop Seeth, they have got him now!" but Seeth was cautious enough to put the diameter of the island between himself and the scene of conflict before concluding to come to a dead halt. The violent struggling of the bear and the dogs had overturned the canoe and thrown them into the water, where the bear, much weakened by the effects of his wound and fall, rapidly succumbed to the vicious dogs, and George and Walter, who had now ventured from the tree, assisted by Seeth, somewhat recovered from his fright, after belaboring him lustily with clubs and stones until there was no signs of life, pulled him upon the island.—"Plumped him fair and square 'twixt de eyes," blew Seeth between his hurried breaths; "but it took him a powerful long time to 'spire." The bear was now dragged into the canoe, and all, including the dogs, were soon afloat.

Considerable surprise was created at the Wheel-hin homestead by the arrival of the boys with proof of an adventure of entirely too serious a character to be passed over without causing some conjectures on the part of the older members of the family, as to what the consequences may have been. Early the following morning, Seeth made his appearance with his butcher-knife and skinned the bear, it being decided that he should have the flesh and Walter the hide, which, with great pride, he took to Richmond, and had an overcoat made of it, in which he had some photographs taken, and sent one to George in commemoration of their perilous encounter upon the island.

A few weeks after Walter's departure he received a letter from George, of which the following is a quotation: "Walt, what do you think? That bear wasn't a real wild one at all, but belonged to an old fellow named Hermiter, who lives three or four miles up the river, and when he found out, after so long a time, that you, Seeth, and I had killed him, why, he just raised the biggest fuss you ever heard of, and Seeth, he's nearly scared to death yet, but says there is no use in making any matter about it now, because he has eaten him nearly all up. Old Hermiter raised him from a little cub, and thought the world and all of him, but he managed somehow to escape from his pen and went to the island purposely for honey, so father thinks. It is very humiliating to be deprived of the honors I have congratulated myself upon winning in an encounter with a ferocious animal, by some one coming and convincing me beyond the least doubt, that he was as gentle and harmless as a kit-

ten. Don't you think so yourself? I have never told it before, but I have always thought it remarkably strange that a wild bear would deliberately climb a tree while two boys were up in it. No wonder father shook his head. I don't expect you will so much appreciate your overcoat after reading this statement of the bare facts."

The Doctor's Talks.

In April last I told you something about the hatching of eggs of the toad and frog, and a little of my experience with hatching the eggs of the hen in an incubator the year before. This spring

Fig. 1.

Fig. 2.

I have had the incubator in operation again, and had much better success than before, probably having learned to imitate the old hen more closely. This time, too, I have been able to observe more of the changes that take place within the egg. In figure 1 in April Talks, was shown the egg as it appears after the first two or three days in the incubator, or under the hen. Figure 1 here, shows the same, but the very beginning of the chick, given separately and magnified. A few days later the creature appears to be all head, as in figure 2, and

Fig. 3.

Fig. 4.

looks as if it might turn out to be a serpent rather than a little chicken. Figure 3 gives the appearance in two or three more days, and it is only after ten or twelve days that we begin to make out any resemblance to a chick, as shown in figure 4. It can not be regarded as a very handsome bird, still we can see the beginning of the bill, the eye looks more like a chicken's eye, while the projections that will be the wings, legs and tail, are plainly seen.

Fig. 5.—THE CHICK READY TO PECK.

By this time the bones have begun to form, and the chick grows so rapidly, that it soon quite fills the shell. Indeed, it has to be doubled up in order that it may be stowed (as the sailors say), in so small a space; the head and feet are brought together, and the chick, as in figure 5, is in a position that looks so uncomfortable, that you would think it would like to get out of it as soon as possible. But it can not come out until the twenty-first day, and it is most wonderful to observe how closely this time is observed by the little prisoners. Many

suppose that the old hen pecks at the shell at the right time and lets them out, but this is not so, the shell is always broken from within. As the chick is doubled up as it grows, the bill is always next to the shell, just where it is needed to break the way out to light and air. It is said that there is a hard, horny scale on the bill, to assist in breaking the shell, which falls away soon after the chick is hatched, but I did not think to look for it. Some of the chicks appear to exhaust their strength with the first pecking, and afterwards are not able to liberate themselves, and unless they are helped they will soon die. When first out of the shell, they are wretched looking objects, their down being wet, they seem to be half naked, and quite unlike the lively fluffy little fellows they are as soon as they get dry. I have often said that you need not look beyond your own farms to find wonderful and interesting objects. Can anything be more full of interest, or a greater wonder, than the formation of a living chick, with its many parts, its blood, bones, feathers and all, out of the almost liquid, and apparently lifeless contents of the egg!

Tree Toads, or Tree Frogs?

One young correspondent wishes to know something about tree toads, and if they are properly toads or frogs. If he means to ask if they are kinds of the common toads and frogs living in trees, I can answer, neither. The tree toads are as different from these, as they are unlike one another, though all belong in the same order, the Batrachians. The creatures are called both tree-toads, and tree-frogs, though most commonly by the former name. Naturalists place the tree-toads in the genus *Hyla*, the one found in the Northern States being *H. versicolor*, the changable-colored, while of the Southern States is *H. viridis*, the green tree-toad. Figure 1 represents the first named, which shows the character distinguishing these creatures from both toads and frogs—the little disks at the end of each of its fingers and toes; these, sometimes called suckers, are supplied with a sticky substance, which allows them to climb upon smooth surfaces of all kinds, even glass. The tree-toad has fine and prominent eyes; the color of this

Fig. 1.—A TREE TOAD.

one varies from pale ash-color to dark-brown, and is marked with blotches of greenish-brown. It has the power of changing its colors to make them darker or lighter, but does not assume any different colors. Like the frogs and toads, the tree toad lays its eggs in the water, and in their younger days they are tadpoles, and during the winter they remain dormant in the mud of ponds, etc. Though quiet during the day, at the approach of evening, they are very active in pursuit of insects. The croak of the tree-toad is familiar to all who live in the country, even if they have never seen the animal. It is heard especially at night, though the creature is not silent during the day. It is a common belief that when their croaking is heard in the

day time it is a sign of rain; but careful observations show that the creature croaks in the day time nearly every day, and though the sound must

Fig. 2.—A FLYING TREE FROG.

sometimes be heard just before a rain, the two have no relation to one another. There is but one tree-toad in Europe, and this is so nearly like our Southern one, that naturalists at one time thought they were the same; it is found also in Asia and Africa. There is found in the Island of Borneo, a tree-frog so curious, that I give an engraving (fig. 2,) of it. It has very long fingers and toes, which are webbed their whole length. By filling its body with air, and spreading its webbed extremities, it can sail from the tops of the highest trees and descend in safety. Though called the Flying Tree-frog, it can no more fly than our flying squirrel, which spreads the loose skin between its fore and hind legs, to break the force of its fall. Both, like boys at coasting, find it fun to come down, but getting back to the starting point is not so jolly. At least I did not used to find it so, and I don't think coasting has changed much in that respect since I was a boy.

THE DOCTOR.

The Floral Wedding.

My friend Mary Gold received, the other day, a letter from her dear John Quill, describing a wedding that was celebrated at the Greenhouse, when the Blue Bells were rung, and Trumpet Flowers sounded. Sweet William and Polly Anthus were the happy pair. The Greenhouse was beautifully adorned for the occasion with vines, and the Virgin's Bowers were all perfumed with lavender and ambrosia, and box after box of bridal presents stood together in long rows. The hour appointed was four o'clock. Dan de-Lion was one of the earliest arrivals. He was much exhausted on the way, and had a wilted appearance. Old Leander and Mother Wort rode together, but when they were passing through Dog Wood, were upset, and the colt's foot being lamed, they borrowed a sorrel horse. The Snapdragons and Thorns were not invited. Earl Sycamore was so sick that his physician, Doctor Moss, would not allow him to go, and so he mustered strength to write, and let his regrets present themselves. The Snowdrops and Snowballs had gone north on a summer visit to the Ice-plants. At length the merry guests began to come in crowds, or flocks, and were received by Madam La Burnham, assisted by the lovely Amoryllis. There were Mr. and Mrs. Orange-blossom, and all their family, and a great many young ladies named Lily and Rose. All the De Luces were there, and a whole troop of Evening Beauties, to whom the Cockscorns displayed their knightly qualities. The most distinguished cavalier was Mr. G. Rani-um, who, as is well known, is the Lady's Delight. Mayor Convolvulus paid his addresses to the wall-flowers, and a Ragged Robin was seen searching for little Cora Andre, who had gone away to play with Johnny Jump-up and his little sister Violet. There was a Mourning Bride, who sadly remarked that when love lies bleeding, no amount of penny royal could ever make up the loss. She wandered off into the garden among the yews and cypresses, and finally sought the society of Weeping Willow.

The Primrose sisters came as dignified and unap-

proachable as ever, and numerous Old Maid Pinks and Bachelor Buttons, looking as aged as century plants, were continually wishing the Balsams would arrive, and inwardly sighed for balm, while the dead leaves of their hopes were rustled by the passing breeze. Lady Teasel and Baron von Tansy made themselves conspicuous by their bitter sarcasm, and the Thistles were so pointed in their remarks that they were driven out with golden rods.

The company became impatient because the Bridal Rose and her Sweet Sultan delayed to come until long past the time, and the joke went mirthfully round as to why Jack-in-the-Pulpit in his clerical attire, did not put in his appearance, but Old Monk's Hood had been engaged to perform the ceremony, so all were satisfied.

At this crisis, Sweet William and Polly came into the large company, followed by Jessie Mine, Rose Mary, Heart's Ease and Love-in-a-Mist, for the charming bridesmaids. The ushers were the Passion Flowers. Nightshade had gathered around, and the Star of Bethlehem shone pale in the light of the new moon, when Crown Imperial, under the linden tree, gave away the bride. After the ceremony the salutations were begun by the Tulips, and sweet congratulations were exchanged by all except Madam Mimosa, who, shrinking in her shivering sensitive way, said "touch-me-not." The dazzling splendor of the scene was magnificently reflected by the Venus' Looking-Glasses. At the ringing of Flora's Bell, a supper was served. There were sweet peas and sugar leaves and honey dew in king's cups, great dishes of pollen, and other delicious things, not omitting to mention the juice of the Madeira Vine. The head waiters were Robin Runaway, Bouncing Bet and Running Rose. Finally there was a grand dance to the merry music of the Canterbury Bell ringers, and they kept this up until the ladies' slippers were worn out.

At this point Venus' Car appeared, gorgeously made of Southern wood, and decorated with evergreen, drawn by ponies named Horse-Chestnut, which the driver, to distinguish them, called Basil and Bay. As soon as the bridal party were in the car, and it began to roll away, that ancient and honorable leather dealer, familiarly called Shoe-Mack, picked up the ladies' slippers and some spearmint, and tossed them after the carriage, while some of the guests rushed on after the prancing steeds, with speedwells and larkspurs, at which the sages retired, disgusted at so much levity. The driver, Michaelmas Daisy, who drank all the currant wine he wanted, put on foxgloves, and away they flew to the docks. The bridal pair set sail on the barque Althæa, expecting to see, after their voyage, London Pride, German Ivy, Rose of Sharon, Indian Cress and China Aster. MIGNONETTE.

Illustrated Rebus.

The Origin of News.

"What do you understand by the word news?" This is a question that was asked me the other day. "Why! something new that has occurred, I suppose," was my reply. "But do you know how the word originated?" I was obliged to confess my ignorance, and imagining my young readers may be as much in the dark, will tell them my friend's ingenious explanation, which she said she came across in an old book, printed long before you or I were born. N, you know, stands for north; E, for east; W, for west; and S, for south; so the four letters were combined together to form the word NEWS, now used for all that is happening north, south, east and west. A newspaper, therefore, tells us by its very name, that it is a chronicle of events in all parts of the world. A. C.

Does the Mulberry Tree have Flowers?

This question is asked by a young friend. He finds very young mulberries on the tree, but never sees any flowers. The flowers are there, though, not being at all showy, they may readily escape notice. The Mulberry and Blackberry, while they look much alike, are very unlike. The Blackberry is preceded by a large, showy flower, and the little grains of which the fruit is made up, are the many pistils of the flower ripened. The Mulberry fruit also consists of numerous rounded grains, but in this case each grain, or little fruit, is preceded by a separate flower. If you examine the Mulberry early enough, you will find what you take for a young fruit, to be numerous small flowers placed closely together on a little stem. To be sure, they are not showy flowers, their parts being greenish, but they have stamens and pistils (in separate flowers), and the ripening of the pistils of many flowers, makes what we call the fruit of the Mulberry.

A Rare Little Plant—Obolaria.

A young man—I suppose he would not like to be called a boy, as he is studying botany—has

A RARE PLANT.

recently sent me from his home in New Jersey, a plant which puzzled him. The plant was about three inches high, of a purplish-green color, very smooth, and in the axils of its wedge-shaped leaves were one to three small purplish or dull white flowers. The plant's botanical name is *Obolaria Virginica*; it is not common enough to have received any other. The name is from *obolos*, a small coin of the Greeks, but there is nothing about the plant that

makes the name appropriate. It is one of the rarest of our plants, and as other young botanists may come across, and be puzzled with it, I give an engraving to help them. It belongs to the Gentian family, though it has but little resemblance to the other members of this family. THE DOCTOR.

Banner Photograph Frame.

In a piece of very heavy paper, not pasteboard, eight and a half by four inches, cut an oval a little above the center, large enough to show as much of the photograph as desired. Cut a corresponding oval in a piece of colored velvet, but a quarter-inch smaller all around. In the two upper corners of the velvet work a spray of yellow wheat with silk floss. Across the lower edge baste a strip of narrow velvet ribbon and work it down with the yellow floss. Along the lower edge make a narrow fringe of sewing silk the color of the band. Thread a needle with the silk doubled several times, sew through the velvet near the edge, tie and cut off at the right length for the fringe. By repeating this across the lower edge, a very pretty fringe is made. Place the velvet flat on a table, lay the paper correctly on it, turn the edges of the velvet up on the paper, and fasten with very thick mucilage. Only the top and two sides are to be turned over; the fringe along the bottom is to hang down. Cut into the velvet around the oval as far as the paper; then turn the pieces over on the paper and fasten them. Fasten a silk cord and tassel to each upper corner of the hanger. The photograph is held firmly in place by taking two or three long stitches across on the back. Suspend it on two brass-headed tacks.

Surplus Fruit—What Shall be Done with it?—Evaporating.

One need not be very old to recollect when the sunny-side of a farm house was festooned with strings of apples hung up to dry, while in front of the kitchen door were trays containing various fruits. Fruit dried in either of these methods is dark-colored, and has been exposed to dust and to the visits of insects. The fruit thus dried, when sent to market at the present time, comes in competition with "evaporated fruit," which sells for several cents a pound higher. "Evaporated fruit" is now a regular article in the market, and we receive many inquiries concerning it. The term "evaporated" is applied to fruit dried by artificial heat, excluded from the light while drying, and sometimes bleached by the use of the fumes of burning sulphur during the drying process. The first evaporating machines were so large, and required such a large capital to run them, that their introduction was slow. Within a few years, there have been introduced portable machines, which, as we know from a trial of one of them, will turn out as salable a product as the large affairs. This year it will probably not pay to barrel and send any but the best apples to market, and all those having a surplus of common fruit, should look about for means of disposing of it. There are but two forms into which a surplus of apples can be converted. One is cider, to be disposed of as such, or converted into vinegar. The other is, dried apples. There are now offered a number of driers and evaporators, which, on a small scale, turn out as good an article as do the larger ones. We have no doubt, that in some peach localities, it may pay for a capitalist to put up a large evaporator. We advise all who are likely to have much fruit to dispose of by drying or evaporating, to investigate the matter, and send to the different advertisers for their circulars. An important point connected with the drying or the evaporating of fruit is, the implements used in preparing the fruit for the drier. Apples, for example, must be pared, sliced, cored, etc., before they are ready to go into the drier. Some of these implements work with wonderful rapidity and perfection. The makers of some of the driers supply all the needed accessories. Not only fruit can be profitably dried, but vegetables

may also be so treated, and these are improved by being prepared in the rapid-working evaporators. Such vegetables as sweet corn, and Lima beans, will be especially welcome on the table next winter.

Plants as Air Purifiers.

Dr. Anders has just concluded some valuable experiments with house plants. He inclosed a dozen potted flowering plants in an air-tight glass case, and placed them in the bay window of a sitting room facing the east. Ozone test papers were hung in the case before it was closed. Observations were made for four hours daily during eighteen days, with results showing the presence of ozone in the air of the case. A second series of tests was made with odorous flowering plants—carnations, heliotropes, etc., with stronger indications of ozone. A third series included "foliage plants"—ferns, dracenas, etc.—with less positive results. Further experiments with plants in flower were made with the case in the out-door air. In these it was found that negative results came on rainy days, thus indicating that bright sunshine is needed to develop ozone. The experiments showed, that the floral organs are specially delegated to the important function of developing ozone. This peculiarly active form of oxygen is produced during the formation of the seed, in connection with the phosphorous compounds there accumulated. Flowers of various kinds have been known to exhibit phosphorescent light in warm evenings.

Ozone is a most wholesome element in the atmosphere, keeping or tending to keep it from becoming polluted with disease germs. It oxidizes, or burns up, noxious accumulations. Plants in flower are therefore to be placed in the front rank as hygienic agents. Ozone is of special value in living rooms, when the air, according to the best authorities, is usually foul. A bay window, filled with flowering plants, will doubtless furnish ozone enough to have a decidedly healthful effect upon the air of the room. It is gratifying to have farther proof that the old-time prejudice against house-plants is ill-founded; instead of contaminating the air of the room, and endangering the health of the inmates, they render it purer.

The California White Cedar.

The term White Cedar, is applied in different parts of the country to three very unlike trees, indeed, they belong to different genera. The tree properly called White Cedar, is *Cupressus thyoides*,

CALIFORNIA WHITE CEDAR.

and more abundant in the Atlantic States than in the interior. Towards the great lakes, the tree generally known as Arbor Vitæ (*Thuja occidentalis*), in more eastern localities is generally called White Cedar. In the mountains of California, a third tree is known by the same name. This is *Libocedrus de-*

currens, our only representative of a genus elsewhere found in Chili and New Zealand. This tree does not occur at a lower elevation than four thousand feet, and above that height it has a wide range throughout the Sierra Nevada and the mountains of Southern Oregon. The height of the tree is from one hundred and twenty to two hundred feet, with a trunk naked for eighty to one hundred feet, and seven to eight feet in diameter. The foliage, as seen by the engraving, bears a resemblance to that of the Arbor Vitæ. The timber of this tree is among the most valuable, at least to farmers, of the many fine kinds of California. It is light, yellowish in color, and of great durability, being in this respect rated above that of the Redwood. For rails, and fencing generally, it is much preferred by the farmers to whom it is accessible, to any other timber. Like many other gigantic forest trees, this, when young, and grown without the crowding that it receives in the forest, is a highly ornamental tree, assuming a compact, pleasing form, and especially attractive on account of the deep, rich, glossy-green of its foliage. This White Cedar has been tried in a number of localities in the Eastern States, and while it does not appear to be sufficiently hardy to be recommended for general planting north of Virginia, yet, with the care given it at Rochester, New York, it succeeds in that rather severe climate. Probably, like many other evergreens, it becomes more robust with age, and if afforded slight protection while young, will soon be able to do without it. The trouble with this, and similar trees is, they continue to grow so late in the season, that their wood does not have time to ripen sufficiently to endure the winter. It is all important that such trees have a light and well-drained soil, and one that is not especially rich.

Temperatures—Practical Hints—Thermometers.

I. H. MAYER, M.D.

There should be a good thermometer in every house. A very little attention to what it reveals to us will be of much practical use to farmers, and indeed to all others. Our feelings are affected by so many internal and external conditions that they are no certain indication of the actual heat or cold. The right temperature of rooms in winter is important. For strong men, properly fed and clothed, this is not so material. To them forty-eight to sixty degrees is felt as comfortable. Young children and aged persons require much artificial warmth. The newly-born infant requires sixty-five to seventy-five degrees, often more. Some old people are benefited by a still higher temperature. The air in a sick room or a hospital should, as a rule, be sixty degrees. Fever cases sometimes do best in forty to fifty degrees.

The importance of the temperature of the water in bathing can scarcely be overestimated. Both vapor and hot water baths above ninety-seven degrees are decidedly stimulant. The warm bath, between ninety-seven and eighty-five degrees, is soothing, and beginning with ninety-seven degrees is suited for infants and of much use in securing a robust growth and laying the foundation for a "good constitution." The tepid bath, between sixty-five and eighty-five degrees, is useful for cleanliness and to promote insensible perspiration—to keep the pores open. The cold bath, between

thirty-two and sixty-five degrees, acts primarily as a stimulant, next as a tonic, and finally as a sedative; though few, except strong persons with healthy lungs should indulge in this luxury. The natural temperature of man in health is ninety-eight to one hundred degrees (98.4 degrees) and exposing the whole body or part of it to water thirty-five to sixty-six degrees colder is unsafe. Well or spring water is usually from forty to sixty degrees, and water to be used for bathing if

NO MORE PIC-NICS.

Drawn and Engraved for the American Agriculturist.

above sixty degrees or below forty degrees should be avoided by the greater part of mankind.

Digestion takes place at ninety-eight to one hundred degrees in man, and in case of low vitality a drink of milk at one hundred degrees or higher is most grateful to the stomach. Fresh water is usually a tonic to the stomach far preferable to any "stomach bitters" or anything else. Ice water, in large or even small quantities, taken by those unaccustomed to its use, paralyzes the functions of the stomach and produces serious results. In experiments in ovens Blagden and Fordyce bore two hundred and sixty degrees, while their own temperature rose only two and a half degrees, but the air was dry and the heat of their bodies was kept down by free perspiration. Higher heat may be endured without discomfort in a dry atmosphere than in districts abounding in moisture. Sixty degrees below zero and even lower has been endured without fatal results. Air at thirty-two degrees contains about ten per cent. more oxygen than at eighty degrees. Hence the vitalizing influence of cold, bracing air, and the rapid breathing or panting of animals on a hot day.

Over one hundred and ten degrees heat of the body indicates the extremest danger in disease, and when the blood of the vertebrate animals exceeds one hundred and thirteen degrees the result is necessarily fatal, as it coagulates one of the albuminous bodies in the muscles. Nearly all, perhaps all infectious material, if thoroughly exposed to two hundred and twelve degrees (boiling heat) is destroyed.

The temperature of a toad and of many varieties of fishes is about fifty-one degrees, and in cold-blooded animals generally it is about the same. The ape has a temperature of scarcely ninety-six degrees; the whale and seal, one hundred and four degrees; and the squirrel, one of the warmest mammals, one hundred and five degrees. That of

the swallow and heron rises above one hundred and eleven; of the hen scarcely one hundred and six degrees, which the incubator must imitate; one hundred and seven is fatal to the chick.

During the flowering process plants evolve unusual heat—in some only a few degrees, while in blossoms of *Arum cordifolium* it rises to one hundred and eleven and even one hundred and twenty-one degrees, while the external air is only sixty-six degrees. Growing plants are slightly warmer than the surrounding atmosphere.

A thermometer is useful in many ways. Milk yields best results if kept at or slightly above forty degrees—the same as good spring water. Cream is most readily churned at from fifty-seven to sixty degrees. Curd cheese is best produced by exposing thick milk at eighty-five degrees. Sweet potatoes keep best if never exposed below forty degrees; while fruit of all kinds requires a room under thirty-five degrees. A cellar for bees should be forty degrees; if well ventilated it may be fifty. A wine cellar about sixty degrees is best, both for fermenting and keeping. Grapes are most successfully propagated from cuttings, single eyes, etc., in a temperature of eighty degrees. In propagating houses for soft wood of various vines and plants the bottom heat should be from sixty-five to seventy degrees, with the air about fifteen degrees cooler than the sand—hot-beds the same or ten degrees bigger. Many other uses will be found for the thermometer besides telling when it is "ninety-eight degrees in the shade" in summer or below zero in winter.

A Farmer's Work-bench.

A cheap and convenient work-bench is shown in the engravings. The legs are of two by six-inch scantling, thirty-four inches long, and the top is made of a two-inch plank in front, and inch boards at the back. Good pine makes a bench that will last many years, and is easy to handle if necessary to use it outside of the shop. In the front are strips, inch or inch-and-a-quarter thick, six inches wide, with the edge bevelled from centre both ways, as shown in figure 1, *a, a*, the slide, *s*, is fitted to move between these strips.

A bench eight feet long, two and a-half wide, and three feet high, is in good proportion. A wide board coming half way or more down the front of the bench is sometimes used, but by making the bench as shown, you can nail in a bottom to the lower strips, and have all the space under the bench for storing tools, boxes, etc. The vise, *v*, should be of hard-wood, about two inches thick, and eight inches wide at the top. The screw is placed

Fig. 1.

as shown in figure 2, and the piece at the bottom is fitted into a mortise and firmly fastened. Cut the four end pieces twenty-seven inches long, and nail them firmly to the legs. Let the two-inch front plank project a little beyond the end pieces, and level the top so that it will be flat and smooth. Set in all the nail-heads an eighth of an inch, that they may not dull any tools. If any of the patent adjustable "dogs" are used, fit them into the plank about ten inches from the end, and six inches from the front edge. A large three-inch screw will answer, but is less convenient. A case of drawers may be made to set in under the bench for holding small tools, brads, screws, rivets, etc.

Fig. 2.

HOME-MADE ESSENCE OF CELERY.—Soak half an ounce of celery seed in a gill of pure brandy for two weeks. A few drops will give a pleasant flavor to a tureen full of soup, or the stuffing for a fowl.

The Best for Butter.

There is but one best color for butter, and that is Wells Richardson & Co.'s Improved Butter Color, no candid investigator doubts. It is the best butter color in the world; is free from sediment or impurity, always ready for instant use, and it imparts to butter that rich dandelion yellow, without a tinge of red, which is the acme of desirability in any butter color.

SUMMER RESORTS.

Elegant Trains—Few Stops and Quick Time—Excursion Rates to All Popular Resorts

The Summer time-table on the New York, West Shore and Buffalo Railway will take effect on Monday, June 23. The accommodations for travel to and from the Catskill Mountains, Saratoga, Lake George, the Adirondacks, Sharon Springs, Cooperstown, Niagara Falls and other resorts in New York are greatly improved. The features that have already made the West Shore route a favorite line for summer travel is the picturesque character of the scenery along the west shore of the Hudson River and the elegance of the passenger coaches and Pullman Buffet Parlor Cars. Special trains have been scheduled which are to be run during the summer without making any but a few necessary stops between New York and the Catskill Mountains, Saratoga and Lake George. Excursion tickets by the West Shore Route and all favorite rail and steamer lines, and embracing all popular river, lake, mountain and seaside resorts, are now on sale at a considerable reduction from regular rates. For time of trains and location of ticket offices please see the Summer Time-Table of West Shore Route in daily papers. A copy of "West Shore Tourist Book," containing hundreds of routes and rates, will be sent to any address on application with three cents in stamps to E. I. BURRITT, Eastern Passenger Agent, No. 363 Broadway, New York.

Practical Forestry.

A Treatise on the Propagation, Planting, and Cultivation, with a Description, and the Botanical and Popular names of all the

Indigenous Trees of the United States,

BOTH EVERGREEN AND DECIDUOUS, WITH NOTES ON A LARGE NUMBER OF THE MOST

VALUABLE EXOTIC SPECIES.

By **ANDREW S. FULLER,**

AUTHOR OF THE "STRAWBERRY CULTURIST," "GRAPE CULTURIST," "SMALL FRUIT CULTURIST," ETC., ETC.

ILLUSTRATED.

In his Preface, the author says: "Many a time during my life have I felt the need of some one volume of moderate size, containing the names and descriptions, however brief the latter might be, of all the trees indigenous to the United States. Having waited in vain for the appearance of such a book, I have attempted to write one myself, with the hope that it will be of service, not only to those who may desire to raise forest trees for pleasure or profit, but to others, who, like the author, may occasionally visit different parts of the country, and need some such guide, that will help them to call to mind the names, as well as to assist in identifying the different species of trees to be found in our forests. I have written it for those who are not supposed to have given the subject of forestry any special attention, and for this reason purposely avoided using any greater number of scientific and unfamiliar terms than was actually necessary in describing the various species and varieties. Furthermore, at the suggestion of the publishers, I have been as brief as possible, in order to make a book that can be sold at a price within the means of all, and one that will not even deter the summer tourist, who is about to spend a few days or weeks in the country, from dropping a copy into his grip-sack before leaving home."

Both tools are guaranteed to give satisfaction, or money refunded; send for Descriptive Circulars, and also for a full Catalogue of the "**PLANET JR.**" Horse Hoes, Cultivators, Wheel Hoes, Seed Drills, and Hand Plows.

S. L. ALLEN & CO., Patentees and Manufacturers, 127 and 129 Catharine Street, Philadelphia, Pa.

NEW SEEDLING STRAWBERRY, "THE HENDERSON."

This new Strawberry originated with Mr. Geo. Seymour, South Norwalk, Ct., who named it in honor of his senior partner, and who also places the variety exclusively with us for distribution. The fruit is of the largest size, early, and immensely productive, but its excellent merit is its exquisite flavor. A beautiful colored plate of the "**HENDERSON**" sketched from nature, we will mail together with Descriptive Circular and Price List, on receipt of a two-cent stamp.

PETER HENDERSON & CO., 35 and 37 Cortlandt St., N. Y.

Cultivators, Feed Mills, Feed Steamers, etc. etc. WHEELER & MELICK CO., Albany, N. Y. Established 1830. Send for Illustrated Catalogue.

The Agriculturist's Microscopes.

They are still coming—the most gratifying compliments as to the superior quality and handsome appearance of the New *American Agriculturist* Microscope.

eroscope, which we have had expressly manufactured for the friends and workers of the *American Agriculturist*. Here are some sample replies:

NEW SMYRNA, FLA., April 30, 1884.

"I have received my Microscope, and I am more than paid for the money that I gave for it. It is just what I have been wanting for some time, and it is just what every one needs."

J. E. THOMPSON.

WETHERSFIELD, CT., May 20, 1884.

"I would also acknowledge the receipt of the Microscope, which came safely to hand, and is a very neat, tasty little instrument."

J. W. GRISWOLD.

ITHACA, N. Y., May 19, 1884.

"I received the Compound Microscope to-day, and after a careful examination, I can cheerfully say it is better than my highest expectations. As to the quality of work on it, the makers' name is a sufficient guarantee for that. Please therefor, accept my thanks."

H. W. SMITH.

YPSILANTI, Mich., May 19, 1884.

"The instrument exceeds anything I ever saw for the amount of money invested in it. It is certainly a marvel."

PROF. J. H. HOPKINS.

FARMLAND, Ind., June 4, 1884.

"The Microscope sent by mail fully meets my expectations."

N. W. WRIGHT.

EWART, Iowa, April 9, 1884.

"Please find enclosed \$1.25 for one of your Simple Microscopes. I am a subscriber to your good old journal, and have the some confidence in you that I would have in a brother. I will get up a club for your paper in some future time."

DANIEL F. WHITE.

This is the season of the year when these Microscopes can be employed to a great advantage by farmers, in very many ways. In fact, one of these Microscopes ought to pay a farmer ten times its cost every year, in the examination of bugs and insects of various kinds, which are injurious to vegetation.

The *American Agriculturist* for March, contains a full description of this new and beautiful Microscope.

If you have not this number of the paper, and would like to see the description, write to us, and we will forward it to you. This Microscope is sent, delivered free, by us, to any part of the United States and Territories for \$2—and delivered free to any actual subscriber of the *American Agriculturist* for 1884, for \$1.25. Furthermore, we will present one, delivered free, and send the *American Agriculturist* to any new subscriber, post-paid, for \$2. Still further, we will present this Microscope to any present subscriber, delivered free to him, if he sends us two new subscribers to the *American Agriculturist* for one year, at \$1 50 each.

How it is Regarded Abroad.

"The London Morning Post," No. 34,947, over a century old, and one of the leading papers of the Old World, thus pleasantly alludes to this journal: "We learn that with the July part of the *American Agriculturist*, Mr. Joseph Harris will attach himself to the editorial staff of that journal. One of the pleasantest of agricultural writers, and with the knowledge that an education at Rothamsted must give, this gentleman is to be congratulated on renewing his connection with the journal that has more of the ring of the domestic hearth than any other Agricultural Journal in the world."

"The Frome (England) Times and Agricultural Journal" for the Counties of Somerset, Wilts, and Dorset, says: "The *American Agriculturist* for July, 1884, is the most superb number of that periodical issued in its 43 years of existence. This is the best and most home-like agricultural paper published, and ought to have a large sale in this country" (England).

Mr. Henry F. Moore, F. C. S., the agricultural editor of the "Times," in a congratulatory communication to the Publishers of the *American Agriculturist*, says: "It is a capital paper."

Do Not Fail

to immediately inform us if your paper does not promptly reach you. Postmasters generally through the country are friends of the *American Agriculturist*, and will be glad to aid you and us in discovering the cause of any miscarriage, whereby your copy fails to reach you on time. The *American Agriculturist* is now mailed as regularly as clock work to all subscribers.

Kind Words.

At no time has the *American Agriculturist* received so many flattering notices from the press and from its subscribers, as now. We thank our contemporaries for their kind words, and our subscribers and friends for their appreciative letters. We have simply to say to one and all, that we shall continue to improve the paper with every issue. The May, June, July and August issues are an earnest of what it is to be in the future. To the old staff of editors and writers who have been with us so many years, we are making accessions, so that the *American Agriculturist* is now stronger editorially than at any former period of its existence. Mr. Allen, the founder of the paper, and for so many years its publisher, may well feel a pride in the success, which this journal, started over 40 years ago, has now attained.

Hon. W. I. Chamberlain, Secretary of the Ohio State Board of Agriculture, writes: "I am glad to learn that Mr. Harris has begun to write for the *American Agriculturist*. I shall begin to take the paper again at once, as will very many others."

Illustrations.

Will contributors invariably bear in mind our request to forward plain and simple sketches and designs with their manuscript. Our artists will make the engravings. The June, July and the current numbers, indicate what the illustrated features of the *American Agriculturist* will be hereafter.

To-Day.

Now is the time to subscribe for the *American Agriculturist*.

You may be busy on the farm, in the garden, or in the household, during July, August, and September.

But those are the months when you may require hints and suggestions, more than ever.

You will find them in the *American Agriculturist*. Then the beautiful pictures in each number will interest you when you come in tired from a hard day's work.

They will both instruct and entertain your wife and little ones.

We propose to make the department for the children more interesting than ever. We want every boy and girl in the land, who reads the *American Agriculturist*, to look forward anxiously every month for its appearance.

And then, when you have read all the interesting things in the Children's Department, we want you to suggest to us anything more that you would like to see there.

Several juvenile subscribers have told us recently that they would like to have the Puzzles and Charades which were formerly in this department.

Well—we are going to oblige you in this respect, and have some more of them from time to time, in the future.

Old Subscribers.

We are now classifying by States, counties and towns, all the vast army of subscribers to the *American Agriculturist* during the past ten years. We expect that every one now living, who is not now a subscriber, will hear from us soon. To this end, will every subscriber within ten years, who is not now a subscriber, and who has within that period changed his post office address, immediately notify us of the fact. The names will then be properly classified under the right Post Offices.

Westward, Ho!

Very many of our readers are writing, thanking us for what they esteem as valuable information, regarding the Far-West.

One of our editors will make his extensive annual tour through the Western States and Territories, in quest of information for those of our readers who are seeking Western Homes, and wish to know the best locality in which to settle.

During the last eighth months we have given a good deal of information regarding Dakota. We propose to give much more.

We invite our readers in that Territory, also in Minnesota, in Iowa, Kansas, and Nebraska, and other Western States and Territories, to send us any information about their localities, of interest. Let it be very brief, however.

Tell us what land is worth per acre in your region, and what the inducements are for settlers. There is a good deal of Government land in some regions of the Far-West, which has not yet been settled. But such portions are growing rapidly in population; and those who wish to obtain a farm of Uncle Sam should not wait too long. The first to come are the best served.

If R. D. Buchanan, formerly of Saginaw, Mich., and for many years a subscriber of the *American Agriculturist*, will send his present address to us, he will confer a great favor upon his devoted daughter, Mrs. Alice Webster.

The Free Recipe Dodge Modified.

Inmann and a number of his followers advertised that they would send a recipe free. A "Medical Institute" in Boston simplifies matters by publishing the recipe in its advertisement. In this, as in those of the other style, care is taken to have in the prescription, or recipe, one or more articles not to be had at the drug stores, at least not by the names given. The "Institute," like all the others, proposes to send the stuff all put up for a consideration. It is the same old story, but a little differently told.

"A Disgrace to the Town."

The people of St. Stephen, in Mass Meeting assembled, have resolved that the Royal New Brunswick Lottery, so often exposed in these humbug columns, is a disgrace to their village, and have applied "to the Government of Canada to take steps to remove the lottery swindle existing in this town." We continue to receive from our subscribers the circulars of these swindlers that are still being scattered broadcast over the United States. After the sweeping exposures made from time to time, surely no reader of the *American Agriculturist* ought to be imposed upon by these scoundrels.

Various Land Companies

In Kansas, Texas, and other States in the far-West, offer lands to settlers on tempting terms. Some of these companies may be all right; others are known to be all wrong. Those who are tempted by these circulars, need not be in a hurry to invest. The land—if they have any—will remain there. Take time, and inquire of the Post-master nearest the alleged locality, as to the Company and the character of the land it offers. Some lands are not worth taking, even without cost. Post-masters have formerly done good service in exposing fraudulent land schemes.

The Spotted Pony Ranch.

The man at Leon Springs, Texas, still sends out his letters, in which he refuses to answer questions about his own business for less than a dollar for a small printed slip. Judging from the proprietor's own circulars, we would not advise any one to go to this ranch to learn the business of ranchero. He signs his name as B. H. Van Raub, and is said to be the same as Byron H. Robb, formerly concerned in various enterprises in Cincinnati, Ohio. Don Carlos is said to be another name for the same person.

No "Lock of Hair" Required.

We have known parties to advertise that they could treat diseases if only a lock of the patient's hair were sent to them. There is a quack in Ann Arbor, Mich., Kellogg by name, who does not even need the lock of hair. He can tell what is the matter just as well, if half a dollar is sent. If full name, age, place of residence, with fifty cents are enclosed in a letter, the sender "will receive by return mail a plainly written statement of his disease, with cost of treatment." The chap says, "It is not necessary that the patient be present to receive treatment," very likely not, we have no doubt that the farther away he is from this "Doctor," the better will it be for the patient.

Brahmo Yan.

Inquiries are still sent us concerning this alleged cure for deafness. One subscriber, Livingston County, N. Y., asks for our opinion of it. Our opinion has already been freely given, and to new subscribers who have not seen it, we would say, that we regard it as most heartless to offer to those afflicted with deafness, this stuff as a "specific." Admitting (which we do not) that this "Brahmo Yan" has any remedial powers in deafness, the affliction is due to so many causes, that any one remedy can touch but a small share of the curable cases. In some forms of deafness, relief by human aid is impossible, yet the sellers of this stuff make no distinction between curable and the incurable deafness. They wish to sell their "Brahmo Yan."

Indignant at the Implication.

Mr. T. W. B., Alexandria, Va., would like to know what sort of people the proprietors of "Churchill's Remedies" are, as they seem to know more about his afflictions than he does himself. He writes us that they write him, "as you have not accepted our offer, etc.," Mr. B. writes us that this is the first he has heard of any "offer," and that he did not before know that he was afflicted with any disease. What right have these vendors of nostrums to insult a stranger by implying that he is in need of their "Restorative" stuff? Have they any right to assume that one has led an improper life, by proposing with their miserable stuff to cure him of diseases, which he does not know even by name? Has one who has lived a quiet and cleanly life no rights which vendors of quack medicines are bound to respect?

Counting Chickens Before They are Hatched.

Some two years ago we exposed the claims of one Bain, of Ohio, who represented himself to be the "North American Poultry Association." This Bain would teach how to make a "Common Sense Incubator" for \$2, and would sell a Havana Recipe for preserving eggs, for some other sum. No one, as we showed at the time, could make a useful incubator from the directions, and the "Havana Recipe" was the old lime-water method, with some utterly useless articles added. During the past few months letters have appeared in papers in various parts of the country, purporting to be written by one L. L. Johnson, Fort Scott, Kans. These letters give most glowing accounts of his success with a "Common Sense Incubator," taking care to tell where to send \$2, for directions for making it. This Johnson pursued his "regular business," whatever that may have been, and claimed that he could easily make \$2,500 yearly from his incubator. As this was quite too good to be true, cautious persons wrote to said Johnson, asking for more definite particulars. The Postmaster at Fort Scott states that, like Sairy Gamp's Mrs. Harris, "There aint no sich pusson," and moreover, that "there never has been any such person as L. L. Johnson in this city." But Bain and his incubator have been thoroughly and gratuitously advertised. Who wrote the letter is not known, but there is no harm in guessing at its authorship.

Caught at Last! One Who Offers Bogus Money.

Circulars are continually sent us by our subscribers, issued by those who apparently offer counterfeit money. This is an old, one of the very oldest traps, but it can only catch those who are dishonestly inclined. An honest man cannot be tempted to touch counterfeit greenbacks, no matter how cheap they may be offered. Having this view of the matter, we for some time dropped this from our list of humbugs, feeling that, should any one get caught in the trap, the verdict of all honest men would be:

"SARVED HIM RIGHT."

We refer to the subject now to show how one of the rascals has been caught, and how our readers who receive similar propositions can aid in bringing the senders of them to justice. Mr. S. Schwartzchelder, Waterbury, Conn., received from one J. C. Stevens, of New York, a circular in which he offered in the usual tempting manner, his "greenleaf articles." Mr. Schwartzchelder consulted the Chief of Police of Waterbury, who corresponded with Mr. Anthony Comstock, inspector of the U. S. Post Office Department. Mr. C. advised that the correspondence with Stevens be continued, and at length some small real bank notes were sent as specimens of the "greenleaf articles" Mr. S. would furnish. The correspondence resulted in an appointment to meet Stevens at the Putnam House, in New York City. At the appointed time Stevens was at the rendezvous to conclude the sale, Schwartzchelder was on hand to exchange a little good money for much not so good. That each man might make sure of the other, the pass-words agreed upon had been exchanged, and all appeared lovely. Schwartzchelder was about to take the "greenleaf articles," but just then Inspector Comstock took Stevens, which essentially changed the aspect of affairs. Stevens was taken before U. S. Commissioner Shields, and having no \$1,000 in good greenbacks at hand—the amount of bail—was sent to jail to await trial upon the charge of violating the law of Congress by using the U. S. Mails for fraudulent purposes.

Offering Bribes.—What Anthony Comstock says.

Louisiana and Kentucky still tolerate lotteries. These States not only allow tickets to be sold, but by granting charters so far give them legal sanction. Were the evil influences of these lotteries confined to the States which

thus countenance them, they would be less objectionable. But the managers of these lotteries appear to think that a charter from the Legislature of their own State gives them the right to carry on their business in other States. Until quite recently, their flaring advertisements appeared in the few New York City papers that would publish them, and their offices for the sale of tickets were open upon the principal streets of the city.

THE THOUSANDS OF DOLLARS

daily taken in by these ticket-offices was not known, until the "Society for the Suppression of Vice" raided its principal office on Broadway, and seized its books, papers, and tickets. It was then found that the daily sale of tickets for twenty days previous to this seizure, reached the astonishing amount of \$5,176 (five thousand one hundred and seventy-six dollars), each day! Besides this, the office received nearly two thousand letters daily. Who contributed this immense daily income to this Company? The "short accounts" of various bank and other officers, and the defalcations of trusted clerks in business houses, are a sufficient answer. It is a well established fact that the annual income of this Louisiana Lottery has been four millions of dollars! What wonder that it can pay big bonuses? The above mentioned breaking up of its principal New York office, was a severe blow to the Lottery Company. Its managers were sensible enough to know that nothing could be gained by fighting the Society which authorized it—What was its next move? A person who claimed to represent the Lottery Company, Mr. Anthony Comstock states to us, appeared at the office of the Society for the Suppression of Vice, and proposed to pay into its treasury annually the sum of

\$25,000 IF ITS SECRETARY WOULD KEEP STILL.

Though the alleged bribe was not taken, the incident shows what "sinews of war" these people can control. But the others having right and law on their side, won the fight.

Some New and Practical Books.

American Cattle, by Lewis F. Allen. A new and revised edition. Orange Judd Company, New York. When this work first appeared as a treatise upon cattle in America, by an American author, who could speak from his own wide experience, it was at once accepted as a standard. There have since been works upon particular breeds, but none comprising all breeds, and treating of them in an exhaustive manner. In subsequent editions, its author, still active and enthusiastic in all that relates to improved agriculture, has kept his work abreast of the time. In the present revision, he has added whatever seemed necessary to maintain the work in the position accorded to it when it first appeared—the standard work upon American Cattle—or more concisely, *Cattle in America*. Price, post-paid, \$2.50.

Ladies' Dogs as Companions, also a Guide to their Management in Health and Disease, with many stories, humors and pathetic, from life. By Dr. Gordon Stables, R. N. Dr. Stables, in his larger work, "Our Friend the Dog," noticed last month, has shown that he possesses two important qualifications as an author. A competent knowledge of his subject, and a most happy style in imparting that knowledge to others. The same characteristics are evident in the present work, which will prove most useful to the increasing number of ladies who choose dogs for their pets, and who are, from a mistaken sense of kindness, apt to spoil them by too much petting and coddling. The same vein of common sense that marks the larger work, runs through the present one, making it a useful guide. Fully illustrated. Supplied by Orange Judd Company. Price, post-paid, \$1.50.

Quinby's New Bee-Keeping.—A new edition by its author, L. C. Root: Orange Judd Company, New York. The title of Mr. Quinby's first work was: "The Mysteries of Bee-Keeping Explained." In the editions which followed, this was simplified to "Quinby's New Bee-Keeping." Each successive edition embodied all the improvements that had been made since the previous one. Soon after the lamented death of Mr. Quinby, his business associate and relative, Mr. L. C. Root, prepared what was, practically, a new work, but with a modesty as rare as it is commendable, continued to call it "Quinby's New Bee-Keeping." In the belief that the great services of Mr. Quinby in simplifying the methods of the Apiary, and in popularizing improved bee-culture, entitled him to be thus commemorated, the title has been continued in subsequent editions. In the present, as in former editions, Mr. Root has added much new matter, and wherever the text required them, new illustrations have been introduced. In its present form it is a standard guide to Bee-keeping as now practised by American Apianians, whose methods are far in advance of those followed in Europe. Abundantly illustrated. In press. Price, post-paid, \$1.50.

Goats in California.—The Angora goat was introduced into California in 1848, and has been bred quite largely upon the common goat. An establishment for making gloves, robes, etc., uses thirty thousand goat skins per year. Other goat raising States of less importance are the Carolinas, Georgia, Kentucky, Tennessee, Texas, and Nevada.

Some Beans.—The United States and Territories produce annually over three million bushels of beans. More than one-third of these are grown in New York. The States next in order are California, Maine, Michigan, Missouri, and Wisconsin. Massachusetts with her famous "Boston baked beans" grows only about twenty-two thousand bushels.

Where to Get Hungarian Grass Seed.—Whenever we recommend a particular crop, we are sure to receive numerous inquiries as to where the seed can be procured. We wish our friends to understand, that, unless we state that a seed or a plant is only to be had of a particular dealer, that seed or that plant is to be procured of all the principal seedsmen and nurserymen in the country. The seed of Hungarian grass, as well as that of all leading grasses, is kept by the principal seedsmen. It is safe to send an order for seeds of any plant in general cultivation to any regular seedsmen.

"Can You Tell Me Where to Get?" Many of our letters begin thus, and then follows the name of some seed. The postal card now before us asks us the question as to Rye Grass, and expects us to answer in the *American Agriculturist*, with the price. Our correspondents should bear in mind this fact: Seedsmen do business to make money, and if they do not have on hand an article that may be ordered, they will procure it, and thus retain a customer. There are numerous seedsmen among our advertisers, and it would not be treating all the others right, to say that any one of the number has a kind of seed that may be obtained from all the others.

Pioneer's Plan for a Rotation of Crops.—It takes from ten to fifteen years in a newly settled region for any rotation of crops to be established. The character of the soil, the wants of the settlers and the market, all determine what crops are to be grown. The farmer will naturally fall into some system of succession for his crops, but the more thought he gives to this subject at the outset, the better will be his future. We do not expect the exact methods of the English farmer on the newly broken prairie. This will come in time, when the virgin fertility is exhausted, and each farm has become a permanent, though small factor, in the national life. We will then need a rigid rotation, and it is well for every farmer, however new his land, to think of what is best for the future, in laying plans for the present. What will your own rotation be? Grass, corn, oats, wheat—does this arrangement best suit your conditions?

Would You Advise the Use of Incubators?—Whiteville Winc Company, Columbus County, N. C. The answer to this question will depend upon circumstances. If it is desired to produce a few dozen of chicks yearly, in order to keep up the usual farm flock, it is better to do it with the original incubator, the hen. If one is to make a business of poultry raising, whether the product is to be marketed as poultry or eggs, and chickens are wanted by hundreds, then it will pay to have an incubator—provided it can have constant and intelligent attention. Among the many incubators advertised, we have tried but one, and cannot say which is the best. Our correspondent will do well to send to the various makers for their descriptive circulars and study them carefully, before deciding which to buy. Many have an electric or other apparatus for the regulation of the heat, others have the heat regulated by the attendant.

THE ONLY machine that received an award on both Horse-power and Thresher and Cleaner, at the Centennial Exhibition; was awarded the two last Gold Medals given by the New York State Agricultural Society on Horse-powers and Threshers; and is the only Thresher selected from the vast number built in the United States, for illustration and description in "Appleton's Encyclopedia of Applied Mechanics," recently published, thus adopting it as the standard machine of this country. Catalogue sent free. Address MINARD HARDER, Cobleskill, Schoharie Co., N. Y.

SIR ROBERT CHRISTISON,

BARONET, M.D., D.C.L., LL.D., F.R.S., Physician to Her Majesty the Queen, President Royal British Association, Professor at the University of Edinburgh, etc., says:

"The properties of this wonderful plant (the Coca) are the most remarkable of any known to the medical world. From repeated personal trials, I am convinced that its use is highly beneficial and tonic."

PROFESSOR DUNCAN CAMPBELL, M. D., LL. D., F. R. S., President Royal College of Physicians and Surgeons, Member General Council University of Edinburgh, etc., etc., says: "Liebig Co's Coca Beef Tonic has more than realized my expectations."

PROFESSOR JOHN M. CARNOCHAN, M. D., Surgeon-in-Chief New York State Hospitals, Professor Surgery New York Medical College, ex-Health Officer, Port of New York, etc., says: "My patients derived marked and decided benefit from the Liebig Co's Coca Beef Tonic."

PROFESSOR F. W. HUNT, M. D., LL. D., Honorary Member Imperial Medical Society St. Petersburg, Russia, Professor of Practice of Medicine, etc., etc., says: "Liebig Co's Coca Beef Tonic is far superior to the fashionable and illusive preparation of beef, wine and iron."

PROFESSOR H. GOULLON, M. D., LL. D., Physician to the Grand Duke of Saxony, Knight of the Iron Cross, etc., etc., says: "It gives more tonic than anything I have ever prescribed."

It is invaluable in Dyspepsia, Biliousness, and Liver Affections.

PROFESSOR G. A. BRYCE, M. D., LL. D., editor *Southern Clinic*, says: "Really a wonderful reconstructive agent, building up the system and supplying lost nervous energy. For broken-down constitutions, it is the agent."

PROFESSOR H. R. BENNETT, of Fitchburg, President Massachusetts Surgical Society, says: "The best tonic to build up a broken-down constitution from long-standing womb disease is Liebig Co's Coca Beef Tonic." It is invaluable in all forms of debility, nervous affections, nervous and sick headaches, and catarrhs.

For indorsements and opinions of hundreds of the most distinguished physicians, irrespective of school, see our circulars.

Liebig Co's Coca Beef Tonic is also valuable in Malaria, Fever and Ague, Chronic Coughs, Kidney Affections, Asthma, Female Irregularity and Sufferings, Palpitation and Weakness of the Heart, Scrofulous Eruptions, Infirmities of Old Age, etc.

The *American Homoeopathic Observer* says: "Liebig Co's Coca Beef Tonic certainly merits all the praise it is receiving."

The *St. Louis Clinic Review* says: "We desire to call the attention of the profession to the reliability of the preparations manufactured by the Liebig Company, and to the high character of the indorsements accorded to this celebrated firm by leading physicians and medical journals of all schools."

The *American Homoeopathic Observer* says: "The Liebig Co's preparations should not be confounded with any patent nostrums. They are legitimate pharmaceutical products, and worthy of the recommendations bestowed upon them by both homoeopathic and allopathic journals."

PROFESSOR J. C. LEHARDY, M. D., President State Medical Society of Georgia, Member Athenae Royal de Bruxelles, etc., etc., says: "The results obtained by me from its use in my practice are indeed flattering."

It embodies the nutritive elements of the muscular fibre, blood, bone and brain of carefully selected healthy bullocks, dissolved in a guaranteed quality of sherry, and combined with the Coca (which is recognized as the most powerful tonic now known) and other valuable invigorating ingredients. It will reconstruct the most shattered and enfeebled, reinvigorate the aged and infirm, and infuse new vitality into sickly children and infants.

PROFESSOR WILLIAM C. RICHARDSON, M. D., Dean of St. Louis, Mo., Clinic of Midwifery and Diseases of Women and Children, says: "To children with marasmus I have given it with decided benefit. It is a remedy of great utility in Dyspepsia. It is also a most powerful and agreeable stimulant to the brain and nervous system, and it is especially useful to counteract fatigue of mind and body."

DR. TUTHILL MASSEY, M. D., L. R. C. P., M. B. H. S., of Manchester, England, says: "The effect is something wonderful. I, non being depressed and very low spirited, easily tired, I can now walk any length of time without feeling fatigue. Before taking the Coca Beef Tonic my nerves seemed so unstrung that when I read a pathetic tale I could not refrain from becoming very much affected, although I tried hard to overcome the absurd feeling. Now I am myself again."

TO THE LIEBIG COMPANY: DEDHAM, ME. Gentlemen—Your agent left me a bottle of your Coca Beef Tonic. I took it myself, as I had been sick a number of months with a lung affection, and was not able to practice. It helped me very much. So much so that I am now about as well as usual. I have since given it to a number of patients, and it has benefited every case. I am indeed most thankful that it came to my hands. I had tried different preparations of Coca before, but had no effects from them. H. S. PHENIX, M. D.

PROFESSOR C. H. WILKINSON, Editor *Medical and Surgical Record*, says: "The Coca Beef Tonic of the Liebig Company, combined as it is with Coca, quinine and iron, forms a most valuable adjunct to the practice of medicine. From the experience we have had with it, we are forced to speak in its favor and to recommend its use. Beef, iron and quinine, cannot be surpassed by any other three ingredients in or out of the dispensatory for invigorating an enfeebled system, and when such remedies can be obtained combined from so reliable a house as Liebig's, it behooves the profession to patronize the same to the fullest extent."

From an article on the Coca by W. S. Searle, A. M., M. D., of Brooklyn, Fellow of Medico-Chirurgical Society of New York, etc., etc.

It is a useful tonic in nervous prostration, hysteria and melancholy. In sustaining nervous force it is superior to all known agents. I have advised its use to a large number and variety of persons for various conditions, and the great majority have found benefit from its employment. To a sufferer from nervous dyspepsia, a lady seventy-three years of age, who had been reduced to a diet of lightly cooked meal and bread, and who for three years had not had a movement of the bowels without the aid of enemata, I prescribed it. Within three days she was able to return to ordinary food, and though two years have passed, she has not

failed to have a regular and normal evacuation daily. A lady who had for years suffered from nervous asthma, and who had been compelled to go up stairs slowly and with frequent rests, found great relief from the very first dose. A broker who had been subjected to excessive nervous strain, and was in consequence unable to sleep or eat well, was becoming weak and emaciated. He greatly feared he would be obliged to relinquish business for a period of entire rest. All his symptoms were immediately cured, and he went on with his affairs as usual. A lady, aged fifty-five, has diabetes. Since taking Coca with her meals she has improved wonderfully, being almost entirely relieved of her former "sinking spells," thirst and constipation. A lady suffered for thirteen years with severe nervous headaches. They at first recurred every three weeks, and finally every two days. She describes them as so violent that she would rather die than live. Three weeks after beginning the Coca she reports: "I have had but one slight attack, and I am so much stronger and better that I feel sure I shall be cured." Many instances of nervous headache, neurasthenia and neuralgia have been reported to me as cured by the Coca when all the usual narcotics, tonics and anodynes have failed to afford relief.

132 HENRY STREET, BROOKLYN.

TO THE LIEBIG COMPANY: Your preparation of Coca is the best I have ever seen. W. S. SEARLE, M. D.

WHAT IS COCA?

The first reply is that it is NOT COCOA.

COMMODORE GIBBON (United States Exploring Expedition of the Amazon) says: "The Coca has properties so marvellous that it enables the Indians, without any other nourishment, to perform the marches of five or six days. It is so bracing, stimulant and tonic, that by the use of it alone they will perform journeys of 300 miles without appearing in the least fatigued."

PROFESSOR J. J. VAN TSHUDI ("Travels in Peru") says: "Setting aside all extravagant and visionary notices, I am clearly of the opinion that the use of Coca is very conducive to health and longevity. In support of this conclusion, I may refer to the numerous examples of longevity among Indians, who, from boyhood, have been in the habit of masticating Coca three times a day. Cases are not unfrequent of Indians attaining the great age of 130 years, and these men, at the ordinary rate of consumption, must, in the course of their lives, have chewed not less than 2,700 pounds of the leaf, and retained the most perfect health and vigor."

I tried Liebig Co's Coca Beef Tonic in a number of cases of chronic dyspepsia where the assimilation of food was very defective and there was steady loss of weight. The results obtained in two weeks were, indeed, flattering. One patient gained five pounds, another three pounds, and so on. J. C. LEHARDY, M. D., Savannah, President Med. Society of Georgia, etc., etc.

Tribune and Farmer,

Established 14 years ago.

THE GREAT AGRICULTURAL WEEKLY OF THE
WORLD, DEVOTED TO THE

FARM, SHOP, AND FIRESIDE.

Cheapest, ablest, most practical Agricultural and Family
Journal published. Edited by a corps of experienced writ-
ters, who know just what they are talking about. Every
number fully illustrated.

The Company publishing the "Tribune and Farmer" take
great pleasure in informing the public that they have now
completed arrangements whereby they are enabled, while
keeping the price of the "Tribune and Farmer" at the low
price of \$1.00 per year, to furnish a mass of original reading,
alike interesting and valuable to the Farm, Shop, and Fire-
side. **Especially attention** given to the Produce, Live-
Stock, and Wool Markets. New departments will be added
from time to time. We are determined to maintain for the
"Tribune and Farmer" the lead that it has attained over
all weekly publications of a similar class.

SUBSCRIBE NOW—Only \$1.00 per year; 50 cents
six months; 25 cents three months.

Sample copies free. Address,

TRIBUNE AND FARMER,

20 Rose St., New York City.

Martin Amber Wheat.

This new variety has again proven its superiority over
older varieties by its enormous yield. Fine quality of
Grain and Flour, and the fact that with ordinary cultivation
it only requires $\frac{3}{4}$ Bushel of Seed to produce 25 to 40 bushels
per acre. The Martin Wheat originated in this locality.
Circular free. Address,
J. L. DILLON, Seedsman and Florist, Bloomsburg, Pa.

Pleasant Greetings.

APPIN, ONT., June 5, 1884.

I think it is the best agricultural paper in the world.
HENRY MURRAY.

NATIONAL, Iowa, June 19.

It is valuable to me indeed; my farm shows it.
J. T. HAMPTON.

SYKESVILLE, MD., June 2, 1884.

It (the *American Agriculturist*) is a wise and most safe
investment.
J. B. BARLOW.

FAIRBANKS, IND., June 9, 1884.

The *American Agriculturist* is excellent, my father was
a subscriber before me, as early as 1859.

GEO. II. HEIMER.

OSGOOD, IND., June 11.

You have the best Agricultural Journal published.
W. T. GOODEN, Editor "Journal."

BEND, TEXAS, May 30, 1884.

I do like the paper; it improves all the time. The
hints and suggestions are a great help in a new country
like this, where agriculture is in its infancy.

M. S. GRISCOM.

CROTON LANDING, N. Y., June 10, 1884.

Allow me to say that your *American Agriculturist*
Microscope is a splendid little gem of great practical
utility. Its benefit to the Farmer and Gardener are in-
calculable. I would not be without it for a dozen times
its cost. It has enabled me to detect the minute germs
that develop the ravaging insects, which I arrested in
time by destroying them by syringe, thus saving cur-
rant, rose-bushes, etc. Every Farmer and Gardener
should possess one. It seems to me that it must come
into general use.
G. STEVENSON.

Replete with useful information and suggestions.—
Baltimore Shipping List.

Well packed with valuable illustrated suggestions. Its
Humburg Department is very serviceable.—*The Hunts-
ville (Ala.) Item.*

The July number is brimful of instructive, season-
able articles, made more interesting and valuable by one
hundred original illustrations.—*Swift Co. (Minn.) Press.*

In all respects a model paper.—*Council Grove Republic,*
Council Grove, Kans.

The *American Agriculturist* for July is filled with
timely and well prepared matter from the pens of thirty-
two of the most noted agricultural writers in the country.
Standing at the head of agricultural journals for forty
years it proposes to yield first place to none.—*New Castle*
(Pa.) *Courant.*

KINGDOM and on the **CONTINENT**.

Messrs. WATERS and RAWLENCE

ARE instructed by **ALFRED MORRISON, Esq.,**
TO **SELL** by **AUCTION** at **FONTHILL**,
WILTSHIRE, ENGLAND, on the 30th JULY and
8th of AUGUST, 1884, the whole of his

WORLD-RENOVED AND SUPERB

HAMPSHIRE DOWN BREEDING FLOCK,

Consisting of about 1,400 very choice *Two-teeth*,
Four-teeth, *Six-teeth*, and *Full-mouthed* **EWES**, 350
ewe LAMBS, and 150 grand **RAM LAMBS** and
SHEARLING RAMS.

Hampshire Down Sheep are now so widely re-
cognized as the *breed of the day*, that the Auctioneers
need hardly point out their highest characteristics,
so essential to Flockmasters, viz., hardy constitu-
tion, aptitude to fatten, early maturity, great weight
and quality both of carcase and wool, combined
with perfect symmetry and color.

The Auctioneers, Salisbury, England (from whom
full particulars may be had), will be pleased to exe-
cute any purchases, free of charge, upon the
money, for payment of any such, being satisfactorily
deposited with London Bankers, and Mr. Morrison's
Agent (Mr. Read) will render every assistance in the
consignment of Stock to any part of the World.

DO YOU WANT A DOG?

If so, send for **DOG BUYER'S**

P. O. Box 289, 31 and 33 Vesey St., New York.

MIXED FARMING IN NEBRASKA.

Grain, Corn, and Live Stock Growing Combined.

The most Profitable and agreeable of any occupation.

1883

Reports prove the agriculturists of Nebraska to have been the most successful of any people in the West.

Write for information about the above matters—also about U. P. Ry. lands in this State, which will be sent Free, in great variety, by LEAVITT BURNHAM,

Land Commissioner U. P. Ry. Co., Omaha, Neb.

Refer to this advertisement.

NORTHERN PACIFIC R. R. LANDS

In Minnesota, North Dakota, Montana, Idaho, Washington and Oregon.

The Northern Pacific country is the newest region open for settlement, BUT THE RICHEST IN NATURAL RESOURCES. Its exceptionally fertile soil, well watered surface, fine wheat and farming lands, best of cattle grounds, large bodies of timber, rich mining districts, healthful climate, great navigable waters, and grand commercial opportunities are the chief attractions which invite a large population.

NOTE 10,818,433 acres or MORE THAN HALF of all the Public Lands disposed of in 1883 were in the Northern Pacific country. Send for maps and publications describing the railroad lands and the country. They are sent FREE.

Address CHAS. B. LAMBORN,
Land Com'r, St. Paul, Minn.

160 MARYLAND FARMS, in Tracts from 30 to 300 acres.

A Profitable Investment!
Each \$5 doubled within 30 days, and loss rendered impossible.

A NEW CITY BEAUTIFULLY LOCATED.

Hindsdale City, adjoining beautiful Garden City—the "loveliest village of the plain"—and Creedmoor Rifle Range, N. Y. Several thousand building lots, surrounding Hindsdale depot, \$185 each, selling on monthly payments of \$5 per lot; four lots, \$10 per month. Prices advanced \$5 per lot monthly until present prices are at least doubled. Cottages \$10 monthly for each \$1,000 of cost. Nuisances and shanties prohibited; no malaria, chills, fevers or mosquitoes; climate, soil, drives and surroundings unsurpassed. Building optional with purchaser; fair dealing guaranteed; nothing over-colored. Buy for investment, residence or Summer home. New York will be

THE FUTURE CITY OF THE WORLD.

Property around it is rapidly increasing in value, and must continue to do so. You enter no uncertain venture by investing in Hindsdale. Prices are low compared with all other New York surroundings; increase certain; prospective value greater than any property of distant. Hindsdale is 13 miles from New York—35 minutes by rail, and 5 minutes additional by Brooklyn Bridge or Ferry; and the commutation averages 10 cents per trip. It is on the main line of the Long Island Railroad, and is the junction for both Garden City and Creedmoor Rifle Range. Improvements proposed, etc., will render Hindsdale an attractive place of abode. Agents wanted of either sex. Circulars, etc., of

R. WILSON, Attorney, 335 Broadway, New York.

THE CHICKERING PIANO

"IS THE BEST IN THE WORLD."

The Chickering has always led in the march of improvement in Piano making. Hence their various styles of

GRAND, SQUARE, and UPRIGHT

Pianos have rapidly grown in public estimation, as is evinced by the number of Chickering Pianos sold since the foundation of the house, which already exceeds

SIXTY-EIGHT THOUSAND.

The highest musical authorities in all lands endorse the Chickering Piano.

AMERICAN AGRICULTURIST,
751 Broadway, New York.

GOOD BOOKS FOR LOVERS OF COUNTRY LIFE.

EITHER OF THESE BOOKS SENT POST-PAID ON RECEIPT OF PRICE.

The Farm.

Farm Conveniences.

Price \$1.50.

A Manual of what to do, and how to do it. Describing all manner of Home-made Aids to Farm Work. Made up of the best ideas from the experience of many practical men. With over two hundred engravings.

Farm Homes, Indoors and Out-doors.

By MRS. E. H. LELAND.

Price \$1.50.

This most charming book should be in every farm home in the land. It is written in a most captivating style by a writer thoroughly familiar with the subjects treated.

The New American Farm Book.

By R. L. and L. F. ALLEN.

Price \$2.50.

This is the best American work upon general farm management. It treats of the leading crops, buildings, draining, etc., and includes sufficient about animals of different kinds to meet the wants of most farmers.

The Saddle-Horse.

Price \$1.00.

A Guide-Book for all who desire to acquire the accomplishment of horsemanship, and who wish to teach their animals how to perform various feats under the saddle. Handsomely Illustrated.

The Horse; How to Buy and Sell.

By PETER HOWDEN.

Price \$1.00.

A Plain and Comprehensive Guide to the various Points to be noted, showing which are essential and which are unimportant.

Silos and Ensilage.

Edited by Dr. GEORGE THURBER.

Price 50 cents.

The Preservation of Fodder Corn and other Green Fodder Crops. Bringing together the most recent information, from various sources. Fully Illustrated.

The Chemistry of the Farm.

By R. WARINGTON, F. C. S.

Price \$1.00.

Treating with the utmost clearness and conciseness, and in the most popular manner possible, of the relations of Chemistry to Agriculture, and providing a welcome manual for those who, while not having time to systematically study Chemistry, will gladly have such an idea as this gives them of its relation to operations on the farm.

Draining for Profit.

By GEO. E. WARING, JR.

Price \$1.50.

So in farm operations, that of Draining is not likely to be treated sufficiently in detail in general works. The two books mentioned are among the most valuable and practical works upon the subject of draining.

Farm Drainage.

New Edition.

By HON. H. F. FRENCH.

Price \$1.50.

Quinby's New Bee-Keeping.

Revised Edition.

By L. C. ROOT. Price \$1.50.

Practical Poultry-Keeper.

By L. WRIGHT. Price \$2.00.

Swine Husbandry.

By F. D. COBURN.

Price \$1.75.

The Pig.

By JOSEPH HARRIS.

Price \$1.50.

Farm Implements and Machinery.

By JOHN J. THOMAS.

Price \$1.50.

Bees, Poultry, and Pigs are often made subjects of especial care by small farmers, and separate treatises on these are more likely to be asked for than those upon the larger animals. Each of these is one of the best in its line.

Most farming operations are accomplished by force, applied through implements and machines, and a farmer should understand mechanics, at least sufficiently to apply force most economically. In this work the fundamental principles are clearly taught, and their application illustrated.

The Garden.

Gardening for Young and Old.

By JOSEPH HARRIS, M. S.

Price \$1.25.

A work intended to interest Farmers' Boys in Farm-Gardening, which means a better and more profitable form of Agriculture. The teachings are given in the familiar manner so well known in the author's "Walks and Talks on the Farm."

The Small Fruit Cultivist.

By ANDREW S. FULLER.

Price \$1.50.

Rewritten, enlarged, and brought fully up to the present time. It is equally adapted to the needs and requirements of the private cultivator and the market grower. This book covers the whole ground of Propagating Small Fruits, their Culture, Varieties, Packing for Market, etc.

Peach Culture.

By HON. J. ALEXANDER FULTON.

Price \$1.50.

This is the only practical Guide to Peach Culture on the Delaware Peninsula, and is the best work upon the subject of Peach Growing for those who would be successful in that culture in any part of the country. It has been thoroughly revised, and a large portion of it rewritten.

Gardening for Profit.

By PETER HENDERSON.

Price \$1.50.

Farms near cities often make more from garden crops than from farm crops. This is the best work on market gardening, and will serve for the family garden also.

Practical Floriculture.

By PETER HENDERSON.

Price \$1.50.

The work is characterized by the same common sense that marks the author's "Gardening for Profit," and it holds a high place in the estimation of lovers of floriculture.

The Fruit Garden.

By P. BARRY.

Price \$2.50.

After the farm crops, fruit is of the most importance. No work covers the whole subject more completely than this. It has been thoroughly revised by the author.

Gardening for Pleasure.

By PETER HENDERSON.

Price \$1.50.

This work was prepared to meet the wants of the amateur in in-door and out-door gardening, and is one of the best guides to Window Gardening.

Play and Profit in My Garden.

By E. P. ROE.

Price \$1.50.

The author takes us to his garden on the rocky hill sides in the vicinity of West Point, and shows us how, out of it, after four years' experience, he evoked a profit of \$1,000, and this while carrying on pastoral and literary labors.

Books on Field Sports.

Florida, and the Game Water-Birds.

By ROBERT BARNWELL ROOSEVELT.

Price \$2.00.

Contains a full account of the sporting along our seashores and inland waters, and remarks on breech-loaders and hammerless guns. Illustrated, and with a portrait of the author.

Superior Fishing.

By ROBERT BARNWELL ROOSEVELT.

Price \$2.00.

Embracing a full account of the Striped Bass, Trout, Black Bass, and Blue-fish of the Northern States, with full directions for dressing Artificial Flies with the Feathers of American Birds; the account of a Sporting Visit to Lake Superior, etc., etc. Illustrated.

The Game-fish of the Northern States and British Provinces.

By ROBERT BARNWELL ROOSEVELT.

Price \$2.00.

The popular writer gives in this book an account of the Salmon and Sea Trout Fisheries of Canada and New Brunswick, together with simple directions for tying Artificial Flies. Illustrated.

Sportsman's Gazetteer and General Guide.

By CHARLES HALLOCK.

THIRD REVISED EDITION BY THE AUTHOR.

Price \$3.00.

Finely illustrated with engravings of game birds and animals, and giving four large maps of game regions. With information of the greatest value to all interested in sporting matters. 1,000 pages.

Our Friend, the Dog.

By GORDON STABLES, C. M., M. D., R. N.

Price \$3.00.

A complete Guide to the points and properties of all known breeds, and to their successful management in health and disease. Illustrated with portraits of Champion and other dogs.

The Dogs of Great Britain, America, and other Countries. New Edition, brought down to date.

Price \$2.00.

It comprises all the essential parts of the two Standard Works on the Dog by Stouehenge, thereby furnishing for \$2.00 what has hitherto cost \$11.25. The book contains over One Hundred beautiful Engravings, embracing the most noted dogs in both Continents.

Field, Cover, and Trap Shooting.

By ADAM H. BOGARDUS.

New and Enlarged Edition.

Price \$2.00.

Embracing Hints for Skilled Marksmen, Instructions for Young Sportsmen, Haunts and Habits of Game Birds, Flight and Resorts of Water Fowl, etc., etc.

American Wild Fowl Shooting.

By JOSEPH W. LONG.

Price \$2.00.

Containing full and accurate descriptions of the Haunts, Habits, and Methods of Shooting Wild Fowl. Instructions concerning Guns, Blinds, Boats, and Decoys. The true history of Choke Bore, and a correct method of testing the shooting powers of Shot Guns. Fully illustrated.

How to Hunt and Trap.

By JOSEPH H. BATTY, Taxidermist.

Price \$1.50.

Enlarged and rewritten by the author. Containing full instructions for hunting Buffalo, Elk, Moose, Deer, Antelope, Bear, Fox, Grouse, Quail, Partridge, Ducks, Woodcock, Snipe, and all the other Game, Water-fowl, etc. Also the localities where Game abounds. With nearly 100 illustrations.

American Game Bird Shooting.

By JOHN MORTIMER MURPHY.

Price \$2.00.

Profusely Illustrated, and describing the haunts and habits of Game Birds generally. 12mo., tinted paper.

Fishing in American Waters.

By GENIO C. SCOTT.

Price \$2.50.

A new edition of this celebrated and popular work, embracing Coast and Estuary Fishing with Rod and Line. Fresh-water Fishing with Fly and Bait, etc., etc. Profusely Illustrated. Cloth, Crown 8vo.

Our New Illustrated Catalogue, with descriptions of all our New and Latest Books, will be sent free on application.

SEDGWICK STEEL WIRE FENCE.

Is the only general purpose Wire Fence in use, being a Strong Net-Work without Barbs. It will turn dogs, pigs, sheep and poultry, as well as the most vicious stock, without injury to either fence or stock. It is just the fence for farms, gardens, stock ranges and railroads, and very neat for lawns, parks, school lots and cemeteries. Covered with rust-proof paint (or galvanized) it will last a life-time. It is Superior to Boards or Barbed Wire in every respect. We ask for it a fair trial, knowing it will wear itself into favor. The Sedgwick Gates, made of wrought iron pipe and steel wire, defy all competition in neatness, strength and durability. We also make the best and cheapest All Iron Automatic or Self-Opening Gate, also Cheapest and Neatest all Iron Fence, Best Wire Stretcher and Post Auger. Also Manufacture Russell's excellent Wind Engines for pumping water, or geared engines for grinding and other light work. For prices and particulars ask hardware dealers, or address, mentioning paper,

AGENTS WANTED EVERYWHERE.

BINDER TWINE

After a test of four years, has the unqualified endorsement of machine-makers and farmers throughout the grain-growing region. It will bind more grain to the pound, with fewer breaks, than any other twine made; is strong, even, free from bunches and knots; and by saving the time of the farmer, is worth double the price of other twines. Ask your agent for "DIAMOND E. BINDER TWINE," and take no other.

This cut represents laying over rough boards our

Rubber Roofing

Costs only \$3.25 per square, 10x10 feet, and will last a lifetime on steep or flat roofs. Send for Book Circular, with references and samples, free.

September.

Among the stubbled corn
The blithe quail pipes at morn.
The merry partridge drums in hidden places,
And glittering insects gleam
Above the reedy stream,
Where busy spiders spin their filmy laces.
The cricket chirps all day,
"O fairest summer, stay!"
The squirrel eyes askance the chestnuts browning;
The wild fowl fly afar
Above the foaming bar,
And hasten southward ere the skies are frowning.
GEORGE ARNOLD.

Onward.

Dr. George Thurber, who for nearly a quarter of a century has been editor-in-chief of this paper; Mr. Andrew S. Fuller, who for a longer period has written for the *American Agriculturist*; Mr. Joseph Harris, who has resumed his editorial connection after twelve years; Col. Mason C. Weld, who for fifteen years has been known to the readers of this journal, and Dr. Byron D. Halsted—comprise a staff, who propose to make the *American Agriculturist* in the future, what it has been in the past—THE LEADING AGRICULTURAL JOURNAL IN THE WORLD. Subscription Price, \$1.50 a year.

Read on page 395 the inducements offered to new subscribers to the *American Agriculturist*, whose names are received before September 20.

The Great West.

This year Mr. Judd again makes his annual tour—a tour sometimes extending as many as ten or fifteen thousand miles—through the Western States and Territories, for the benefit of those readers who desire correct information regarding this vast region of country. From Dakota he writes that at no time during seven years can he recall such magnificent crops as everywhere greeted his eye from New York to the Missouri River. As a general thing, people are in good spirits, and the financial depression prevailing during the mid-summer at trade-centers, does not extend over the country to any great degree.

We are now giving in every issue of the *American Agriculturist*, over one hundred illustrations of inventions and labor-saving devices of every character, for the farm, garden and household; also original pictures from every day rural life, which not only please and instruct, but develop the taste for what is beautiful and elevating in this world. Time was, when farm labor was considered mere drudgery. It is a pleasure to know that this journal has materially aided in making the pursuit of agriculture so attractive, that nearly every business man now in our large cities, looks forward to the time when he can own a little place for himself in the country, be it ever so small.

"I do not understand how you can afford to furnish the *American Agriculturist* at \$1.50 per year," said one of the owners of the first illustrated paper in America to us a few days since. It is a remark very often made by publishers, as well as readers, of various other journals. We shall continue, however, to supply this periodical at this price, notwithstanding the new departments and new features constantly being added. We may observe, however, that the *American Agriculturist* could not be afforded for double the price, were it not for our very large subscription list and advertising patronage.

Editors, Agents, Canvassers, and Subscribers are referred to p. 395, for matters of special interest.

Three Months' Subscription to this Periodical for Nothing. See page 395.

The yield of wheat depends largely upon the tillering, therefore sow early on rich, mellow soil. Wheat needs to make a strong growth of roots before winter. Use superphosphate or other commercial fertilizer, when there is not sufficient barnyard manure. Lime may be added to soil rich in vegetable matter. Its chief value is in liberating other elements of plant food. As a preventive of rust, wet the seed grain in strout brine, or a solution of four ounces of blue-stone (sulphate of copper), to a gallon of water. Sow with a drill when possible. If the wheat land is not well drained, make the water furrows with the plow after all else is done. These will quickly carry off surface water after hard rains. Grass seed may be sown a few weeks later. Clover is best sown in spring, and the seed may be scattered on the last snow.

The best way to harvest corn is to cut the stalks close to the ground, and place them in shocks. A "shocking horse" is almost indispensable in setting up corn so that it will stand. Willow, or other tough withes are excellent for tying the shocks when the stalks are not suitable. The seed corn should have been selected in mid-summer, but if delayed, neglect this important work no longer. Carefully decide what are the superior points in the corn desired and choose that. This can be best done while the stalks are standing. Go through the corn field and cut the selected stalks and place them in separate shocks.

Buckwheat should be harvested before frost can injure it. Cut it in the morning when the dew is on, to prevent shelling. Thresh as soon as the straw is sufficiently dry, and spread the grain thinly upon a floor, as it may heat in a large heap.

Harvest potatoes when ripe, and before hard rains induce new growth, or cause them to rot.

LIVE STOCK NOTES.—One of the leading requisites for health and thrift in live stock, is regularity in feeding and watering. Both the quantity and quality of food should be uniform. Pastures are now beyond their prime, and need to be reinforced by roots, fodder-corn, or other green food. Any falling off in condition in farm stock should be strictly guarded against as cold weather approaches. Young animals profit much from any extra feed during the first year. Horses after a day's work enjoy being sponged with clean water containing a few drops of carbolic acid. After the regular feed, they may pass the night in the pasture. Look well to the feet and the shoulders of work-horses.

SUNDRY MATTERS.—Clean up all rubbish about the yards and buildings, and store all farm implements not in use in a dry place. Do not think lightly of the fairs, but compete for some of the premiums. Make it a point to go to at least one exhibition and take the family. Prepare storage room for roots and other late crops, and be well ready for taking in the live stock when cold weather comes and autumn storms threaten.

Orchard and Fruit Garden.

Gathering and marketing will be an important work. Good fruit, neatly and honestly packed, will always bring good prices in seasons when poor fruit will not pay its freight. . . . Pick all pears before they become mellow. . . . The longer the peaches will be in reaching the consumer, the harder should they be when picked. . . . Small local markets often pay better prices than those of large cities. . . . Recollect what has been said about drying or evaporating fruit. . . . Budding of peaches and pears on quince stocks, should be completed. See that the ties are cut in season. . . . Stones of peaches and plums, if in small lots, may be kept in boxes of sand in a cool cellar. . . . Where fall planting is desirable, prepare the land and order trees at once. . . . Cut away blackberry canes as soon as the fruit is picked; do not allow new canes to grow higher than six feet. . . . Strawberry plants layered in pots may still be planted. Keep the runners from new beds, unless more plants are wanted. . . . Grapes should be packed according to the customs of the market to which they are sent. Small fancy paper boxes, and baskets holding ten or twenty pounds, are now popular. . . . Attend to late insects.

Market and Kitchen Garden.

This should be a month of abundance on the table and in the markets. . . . In preparing vegetables for market observe the preferences of the place where they are to be sold. Wash all roots; better feed them out at home, than send to a city market unwashed. . . . Warm days and cool nights favor the growth of cabbages, celery, etc.; also the growth of chick and other weeds, and the hoe and cultivator will be frequently required. . . . Sow early cabbages, cauliflowers and lettuce, for plants to winter in cold-frames. In most places lettuce plants will keep without glass if covered with leaves. . . . Sow spinach, kale, usually called sprouts, winter radishes, corn salad, and flat turnips. . . . Cut cucumbers for pickles when of the desired size, every other day, always with a stem. . . . When melons are ripe, they part readily from the stem; the ripeness of watermelons is usually told by the hardness of the rind. . . . Late tomato blossoms can not now produce fruit that will ripen; cut them away. . . . Only the celery needed for immediate use or sale, should be earthed up for blanching; it is too early for the main crop. . . . As soon as a crop is off, gather the refuse for pig or cow, and prepare the land at once for some winter crop.

The Flower Garden and Lawn.

The lawn should be mown according to the condition of the grass, rather than at stated periods. See article page 362 on "Lawn Making." . . . Stake tall-growing plants, dahlias, tuberose, lilies, etc., against strong winds. . . . Pot chrysanthemums for house blooming; those to remain out will require stakes. . . . Plant hyacinths, narcissuses and other "Dutch bulbs," as early as they can be purchased. . . . Sow seeds of perennials as soon as ripe. . . . Make cuttings of bedding plants; the old plants are seldom worth taking up. . . . Violets should be planted in frames to be covered with leaves in cold weather. . . . Gather seeds as they ripen, label at once, and as soon as dry and cleansed, store in paper bags in a dry place away from mice.

Greenhouse and Window Plants.

The houses and heaters should be ready for immediate occupation. . . . Potting soil, sand, pots and all things needed for winter use are to be stored under cover, or in the cellar. . . . Plants to be taken up from the borders for winter blooming, should now be potted, cutting back both top and roots. . . . Re-pot those plants that have been in pots all summer. . . . See that pots and plants are clean when taken in. . . . Sow annuals for winter bloom, pot bulbs, and make cuttings of geraniums, etc.

WHERE ARE THE BEES THE BUSIEST?—Our yearly honey crop is about twenty-six million pounds, of which Tennessee produces over two millions, followed closely by New York. Ohio comes next,

and then North Carolina, Kentucky and Pennsylvania. The other States producing over a million pounds are Illinois, Iowa, Virginia, Georgia, Michigan and Arkansas. The honey interest is widely scattered, and there is room for it to become still more so, to the benefit of plants as well as man.

Thatching Roofs with Straw.

Several of our readers ask us for directions for roof-thatching with straw. A well-made thatched roof is water-tight, durable, warm, easily repaired and especially adapted to prairie regions, where shingles are expensive. The straw employed in making the roof should be hand-threshed, and dampened before it is used. The roof-laths may be saplings, two inches thick, and flattened where they cross the rafters, to which they are nailed. The straw is prepared in small bundles, with the butts evenly arranged, and are tied to the lath with tarred twine, using a wooden needle. The bundles are laid in tiers, beginning at the eaves in the same manner as with shingles. The peak is covered by bending the straw in the middle, and sewing the ends to the thatch on each side.

A Watering Tube.

Mr. G. W. Jerrard, Aroostook Co., Me., sends us a sketch and description of an implement for watering garden plants. It is a tin tube, shown at *a* in the engraving, one-half inch in diameter, eight inches long, perforated near the bottom, and with a conical end. The upper end, *b*, is in the form of a funnel. In using this device, insert the conical end of the tube in the ground as near the plant as convenient, without disturbing the roots, and turn the water into the funnel. The water will pass out into the soil through the perforations at the bottom. The soil is not baked on the surface when watered in this manner, and the operation is very quickly done. Any local tin-smith can make the tube at a slight expense. A small flower pot is sometimes sunk in the soil near the plant, and the water, when poured into it, will gradually soak away.

A Fruit Ladder.

An orchard ladder should be both light and strong. Mr. H. H. Hawes, Kennebec Co., Me., sends us a description of such a ladder. The sides may be of two by three-inch spruce, shown in section with trimmed corners at *a*. The "rungs" should be of hard-wood—white oak or white ash, a trifle more than an inch in diameter, and placed

A FRUIT LADDER WITH MOVABLE FOOT.

thirteen inches apart. The bottoms of the side-pieces may be left square, and on one rivet an iron band. Fasten a similar band to a hard-wood piece twenty eight inches long, and nearly the size of the ladder-side. Small holes are bored through this piece and also the ladder-side, in which is placed an iron pin, *b*. By means of this device the ladder can be quickly adjusted to the unevenness of the ground. This movable foot can be removed.

Making a Straw Stack.

JOSEPH HARRIS.

As soon as the threshing machine comes on to the farm, one of the first questions is, how large shall we make the bottom of the straw stack? If you ask the threshers, they will say, "Be sure and make it big enough." But if you want to save all the straw you can, a much more sensible answer would be, "Be sure and make it small enough." If you have more straw than can be got on to the stack, it is an easy matter to put a wagon by the side of the stack, and draw a few loads to the barn. But if you run short of straw, you cannot possibly top off the stack properly.

Barley, oats, and pea straw is frequently so much broken up by the machine, that it packs closely, and occupies far less space than rye and wheat straw. Of wheat and rye straw it will require about one thousand cubic feet of stack room to hold a ton, and a yield of twenty-five bushels per acre may give you a ton of straw. Occasionally a heavy crop of wheat will give one hundred pounds of straw to each bushel of wheat. When wheat, rye, barley, and oats straw are stacked together in anything like equal proportions, we shall not be far wrong in estimating, on the average, half a ton of straw to each acre. Furthermore, in such a case eight hundred cubic feet of space will be sufficient per ton. In other words, a stack eleven and a half feet in diameter will hold about an acre to each four feet in height. One thirteen feet in diameter will hold an acre to each three feet in height; one sixteen feet in diameter will hold an acre to each two feet in height; one twenty feet in diameter, will hold about an acre to each one and a half foot in height, and one twenty-three feet in diameter will hold an acre (a half a ton of straw), to each foot in height. A stack thirty-three feet in diameter, will hold one ton of straw to each foot in height; one forty feet will hold one and a half ton to each foot in height.

When you have decided how large a stack to make, place a fork in the centre. Tie a string to it, and if the stack is to be forty feet in diameter, tie a knot in the string twenty feet from the fork, and hold it in your left hand. Spread out the straw on the bottom of the stack a little farther than it ought to be, and then pass round the stack and push in the straw with the feet, until the circumference is twenty feet from the centre. It is little work, and is far better than trusting to the eye.

In building the stack, the main point is to keep the middle full and well trodden down. The chaff and the straw that is broken up into small lengths is more compact than the long straw, and should be kept in the middle of the stack. Place the long straw on the outside of the stack, and also bind it with long straw. It is neither safe nor desirable to tread down the straw on the outside. The lighter it is the more it will settle, and the better it will shed the rain. This is particularly important after you commence to build the top.

Until we get longer straw carriers, we must do the best we can with those we have. As we approach the top, the straw carrier leaves the straw nearer the outside of the stack, and the man who throws it back can hardly avoid removing the long straw and leaving the chaff. Take special pains to remove the chaff, and to pack long straw under the carrier.

When threshing, the farmer should avoid, if possible, taking any steady work that will confine him to one spot. He will find plenty to do in strengthening the weak spots, in helping where help is most needed. This will frequently be at the straw stack. The outside should be raked down, and the straw thrown on to the carrier. Frequent visits to the top of the stack are desirable, if for no other purpose than to see that the middle is well trodden down. When the stack is finished, hand the stacker some "riders" to hold down the straw, and prevent the wind from blowing it off. Rails securely tied together with wire or rope will answer the purpose. Twisted hay or straw ropes are sometimes used, but it is not pleasant to have a rail slip down on to one's head. Raking the top of the stack until the straw slants down, makes the stack almost as safe against rain as if it were thatched.

Feeding and Care of Farm Animals.

PRIZE ARTICLE.—BY "A WESTERN FARMER."

Cattle.

Every intelligent farmer provides stables or good sheds for his cattle. They should be warm, light, and well ventilated. For cow stables, floors of plank, very slightly inclined to the rear with a deep gutter are best. Windows and ventilators should be fitted with sliding shutters, and be covered with wire screens to keep out flies in summer. For litter use any dry material—straw, forest leaves, saw-dust, dry sods, etc., etc.—that will absorb the liquids. Sheds should be enclosed on all sides, and have wide sliding doors, which may be closed in very cold weather and in fly time. Grade the floors to slope to one side. All mangers need to be grain-tight, with bottoms at least twelve inches above the floors.

Well cured Timothy and clover are best for hay. The coarse grasses, Hungarian, Millet, etc., are excellent if cut just before or at the commencement of blossoming, properly cured and stored in a dry place. Clover and these coarse grasses are best kept in narrow hay-sheds, well ventilated at the sides and having a floor, of poles or rails, raised eighteen inches above the ground. Clover can be cured in such sheds much better if put in alternate layers with wheat or oat straw, or any of the coarse grasses. When hay or other coarse food is scarce, clean, bright straw may be used. It should be cut short, dampened, and have oil-cake meal or oat-meal and bran mixed with it, when stock will eat it clean and do well on it. In feeding hay in the stable, a cutter is almost indispensable. Hay fed in the yard is best uncut.

Sweet corn makes the best fodder corn. Field corn is very good. Unless properly harvested and stored, it rapidly deteriorates. A shed for its preservation is shown in figure 1. This shed is sixteen feet wide and thirty-two long, nine feet high at the sides, and twelve in the center. The floor is of four-inch boards, laid an inch and-a-half apart, eighteen inches above ground. There are sliding doors at one end, and a window at the other. The fodder is separated into four-foot divisions by movable posts, which fit into slots in the floor and ceiling. Figure 2 shows the ground plan with the shed filled, except the two center divisions reserved for sheaf oats. The corn should be cut just as the grain is hardening, placed in shocks, and allowed to cure six to ten days, according to the weather. It is then bound into convenient bundles, with

Fig. 1.—A FODDER SHED.

straw or twine, and stored in the shed. The lower end of the stalk is worthless, therefore cut twelve to twenty inches high, according to length of stalk.

Corn should always be used with coarse feed. Shell it; nothing is gained by feeding it on the cob, but often much lost. For calves it is best cracked or coarsely ground and mixed with oats or bran.

Sheaf oats are an excellent feed, or for variety when hay is scarce. If cut as soon as ripe, bound in medium-sized sheaves, and stored in sheds similar to corn fodder, the straw will be nearly equal to hay. Run through a feed-cutter, and mixed, stock will eat the whole and thrive upon it.

Oil-cake meal, corn-meal, oat-meal, and cottonseed meal, are all excellent for cattle when fed judiciously and with plenty of coarse feed. A very successful feeder has met with the best results with the following mixture: Two hundred and eighty pounds of shelled corn, and one hundred and twenty pounds of oats are ground together, one hundred pounds of oil-cake meal added, and

the whole thoroughly mixed. This is fed twice a day, half a pound for each one hundred pounds of live weight of animal. With this and good hay a thrifty grade Shorthorn, two years old, ought to make a gain of about three pounds per day.

There is no doubt that ensilage, when properly "cured," and fed in combination with other foods, is an excellent article for live stock.

Roots.—The value of the root crop can hardly be over-estimated. Of mangels, the Yellow Globe seems to be the best keeper. The Loug Red variety will generally give a greater yield to the acre on rich, deep soil, but the roots are far more difficult to harvest and handle. There is no great differ-

Fig. 2.—GROUND PLAN OF FODDER SHED.

ence in the value of mangels and beets for feed. Carrots are valuable for both cattle and horses. When stored they should be "ricked" up like stove-wood; they keep better, and room is economized. The Half-long is an excellent yielder and easy to harvest. A good, roomy root cellar is indispensable to every farm.

The best pasturage is Kentucky Blue Grass and Red Clover. It is the earliest and also the latest. On rich soil we have seen one acre keep two cows in fine condition through the whole season. A mixture of Red Clover, Orchard Grass, Meadow Fescue, and Timothy, makes a very satisfactory pasture. Do not graze a pasture so close that the sun will destroy the grass, or the frosts heave it out.

Care of Milk Cows.

Have the stable so arranged that it can be darkened for the cows in fly time. Provide abundance of pure water. They must have this to give sweet, pure milk. Keep salt where they can obtain it at all times. If pasturage gets short in late summer, feed green corn, clover hay, chopped roots, or meal at evening. Keep up their condition by all means; remember winter is approaching. Immediately after the oat crop is harvested, the land may be plowed and sown with corn, either broadcast or in drills, and it will make capital fall feed, much better than turnips. If frost is likely to catch any of it, cut it and bind it in small bundles. After curing, store it in the fodder shed.

In winter provide a warm stable, bed well, and keep clean. In very cold weather give tepid water to drink. Turn the cows out for an hour at mid-day. Supply all the food they will eat. Mix and vary it as much as possible, to keep up a steady flow of milk. Well-fed cows give rich milk; half-fed cows, poor, thin, blue slop. To fasten a cow in the stall, buckle around her horns, or neck, a leather strap two inches wide, having a ring attached. To the mauger tie an inch rope with a snap fastened to the end. The ring and snap can be quickly connected or disconnected. If you value the comfort and health of your cows, do not use that instrument of torture, the stanchion.

Have regular hours for milking. We always obtain the greatest yield by milking while the cows quietly eat their meals in winter, and while they chew their cud, or lick a little salt in a dark shed in summer. A good milk pail is a four or six gallon can, having a movable cover with a hole in one side of it. Set a five inch strainer funnel in the hole and milk into it.

After a cow has been served by the male, it is best to keep her in a stable away from other cattle twenty-four hours. The period of gestation varies somewhat, two hundred and eighty-five days being the average. For two weeks before calving, feed very little grain of any kind. Hay, potatoes, mangels, carrots, etc., are best to keep the blood cool, and the system relaxed in winter.

CALVES.—Calves do best when allowed to suck the cow. One cow should raise two calves. They should be suckled or fed three times a day until about seven weeks old; after that twice a day will

do. Never allow them to run with the cow. It is much the best plan to never let the calf suck a milk cow. Milk her, and feed the milk while warm to the calf. In about a week it may be mixed with sweet skim milk, about half-and-half, gradually increasing the latter as the calf grows older. So soon as it shows disposition to eat, supply it with oat-meal and bran mixed wet, or the "chop stuff," now ground at most flouring mills, and bran, wetted and mixed in about equal proportions. Either of these feeds will sour in about twelve hours after being mixed; keep it fresh, and wash out the feed box. Oil-cake meal, in very small quantities, mixed with bran and corn-meal, is very good. Tie a small bundle of hay before it, and renew when it has picked out the best. A mangel, or a few potatoes cut small, will be relished and keep the bowels open. Put the calves on pasture as early as possible. Never allow them to run down or become thin in flesh. A small feed of corn-meal or shelled corn, oats, or "chop stuff," and bran every evening will keep them in good, thriving condition. In winter vary their food, and keep them warm. See that they have plenty of good water, also salt. Bulls should be rung when six months old, and thereafter kept separate from heifer calves. Plenty of uncut hay, with some corn-fodder or sheaf oats, and a little grain feed is best for them in winter.

Nearly all diseases to which live stock are subject, are the result of neglect of the simplest sanitary rules, and may be prevented by the exercise of a little common sense. Never compost manure in a cellar beneath the stables, nor in an adjoining shed. The foul, noisome gases arising from the rotting mass, will poison the air throughout the entire building, and to compel animals to breathe it is the height of folly. Fancy ventilators and clean floors will not remedy the matter. Manure and all decaying matter must be removed to a distance from every part of a building, to keep it fit for live animals. Farmers who neglect these simple precautions need not be surprised if strange and fatal diseases frequently break out among their stock, and inflict upon them great loss. The fault will be theirs alone. Never under any circumstances change any kind of stock suddenly from one kind of food to another which they are not accustomed to. Great and often permanent injury may result. Let such changes be gradual. For the treatment of bloat, use a trochar and canula. Every farmer should have them. They are cheap and are often the means of saving the life of stock. Full directions for use accompany them, and any hardware dealer can supply them.

When a cow or calf is seen choking, grasp it and feel along the outside of its throat for the hard substance. When found, exert vigorous pressure, and slide the article up into the mouth. For scours in calves, feed new milk (heated near to the boiling point, and allowed to cool sufficiently) with oats, bran, and corn-meal dry until cured. Heavy milkers are most liable to garget. We prevent it by milking once a day the last month of pregnancy, and feeding cooling, relaxing food. Fomenting the udder once a day with tepid water is a great help. Watch the udders of pregnant cows for indications of garget, and relieve promptly. In three different instances we found it necessary to regularly milk young heifers, of a strain of heavy milkers, nearly a month before dropping their first calf. A neighbor having one of the same strain refused to go "contrary to nature," as he termed it, and the animal was ruined. In every case, after the calf has sucked the first time, the udder should be drained of its last drop. This should be done regularly twice a day until the calf takes it all.

REDUCING BONES.—Sulphuric acid is the agent employed in reducing bones to a superphosphate. It is a very corrosive liquid, and when of full strength, will quickly destroy any flesh or clothing it may touch. Unless a person is fully acquainted with the dangerous qualities of the acid, we unhesitatingly recommend him to leave it alone. Bones may be burned, and the ashes scattered upon the soil at the rate of two hundred pounds per

acre. Green bones mixed with unleached ashes, and kept moist, will soon become soft, and may be broken up with a spade and applied to the land.

Weaning and Feeding Young Pigs.

Pigs should gradually be weaned, and fed in a separate pen. If kept in a field, make a small enclosure for them. When managed in this way, pigs will continue growing when the sow fails to afford sufficient milk. Overfeeding at weaning time, is injurious. The pigs gorge themselves and become ill-shaped. They should be fed a little, six times a day. Pigs with disordered stomachs can not thrive. Inflammation of the bowels is a common disorder, and is caused by over-eating, unwholesome food, and exposure to cold. Food much fermented will induce inflammation of the stomach and bowels. This is the cause of much mortality among hogs fed with slops from hotels, asylums, etc., where there is a large amount of fermented material mixed together in the swill-vats. The same condition may follow the feeding of much corn, with but little exercise in the open air. When there is access to green food and the soil, young pigs may be fed corn more largely. People now

A FEEDING PLATFORM.

wish more lean pork, and the skilled swine growers should recognize this desire and act accordingly. The more high-priced pork they can sell, the more profit they will realize. Fine wheat middlings make the best ground feed for young pigs.

The form of the trough is important. It should be so constructed that the pigs cannot get into it with their dirty feet. Nail slats across the trough so that the pigs cannot crowd each other. Feeding on the ground is shiftless and wasteful, especially corn or small grain. Always place the dry food on a platform in a high, dry spot. The platform should be large enough to accommodate the pigs without crowding. The grain may be kept on the platform by a narrow siding. Such a platform as shown in the engraving will last for years, and save much grain from being wasted. The platform should be frequently swept clean. When not in use, it may be turned up edgewise to prevent decay. The bottom boards are nailed to stout scantlings, which rest upon flat stones. F. D. CURTIS.

A Cheap Picket Fence.

In localities where sawed lumber is expensive, and split timber is readily obtained, a very neat picket fence may be made with little outlay, by using round posts, split stringers, and rived pickets, as shown in the engraving. The stringers are eight to twelve feet in length, and usually one of the flat sides is sufficiently smooth for receiving the pickets. Let the stringers project a few inches beyond each post, adding strength to the fence, and should the posts decay, new ones may be driven in upon either side, and the stringers readily at-

A FENCE OF SPLIT LUMBER.

tached by heavy nails or spikes. With timber that splits freely, a man can rive out five or six hundred pickets in a day. The construction of the fence is plainly shown in the above engraving.

Field and Sweet Corn.

The varieties of Indian corn are without number, but they may be all placed in two classes as regards the chemical composition of the grain, viz., field and sweet corn. The average composition in one hundred parts of these two classes is as follows:

	Albuminoids.	Fibre.	Carbohydrates, Starch, Sugar etc.	Fat.	Ash.
Field.....	12.	1.9	78.7	5.7	1.7
Sweet.....	13.2	2.3	73.5	8.9	2.1

It is seen that sweet corns contain more albuminoids, fibre and ash, and much more fat than common or field corns. The additional amount of albuminoids and fat give the sweet corns their much desired superior richness.

The flint and dent corns have practically the same composition, there being one-half per cent more water in the dents than in the flints. There is no marked difference in the composition of eastern corns, or northern and southern sorts. The southern grown varieties are considered superior, and more is paid for them by the starch factories. They are better ripened, sounder and dryer, yield more starch, and make better bread. The differences are more mechanical than chemical.

Pop corn is any sort, the grains of which will burst open when they are heated. It is a popular error, that pop corn contains a larger per cent of oil, which decomposes and volatilizes with heat, and thus bursts the grain. Analyses show that there is no excess of oil over that in common varieties of corn, and none of this is lost in the process of popping. Professor Brewer found 4.79 per cent of fat in one variety of pop corn before popping, and 4.94 after; in another 5.59 before, and 5.67 after. Both popped particularly well. A hard flint variety (Wanshakum) contained 4.67 per cent of fat; the same after roasting had 5.14 per cent. The oils instead of volatilizing and escaping, probably absorbed oxygen during the heating. Only hard, compact varieties of corn will pop; this peculiarity is due to the bursting of the closely confined starch grains, caused by the expansion of the contained moisture, and the sudden rupture of the hard outerpart of the grain.

Color has little or no influence upon the composition of corn. It varies from milk-white to yellow, chestnut, indigo, and black. Soft varieties are best for feeding whole to farm stock. There is considerable waste in using old flint sorts underground. Corn on the average is not so rich as wheat in albuminoids; but the most noticeable difference is in the amount of oil. The fats in wheats range from 1.26 per cent to 2.67 per cent, while in corn from 3.40 per cent to 9.31 per cent. It is easy to see that corn is a very fattening food.

Green sweet corn is more nutritious than field varieties, and contains from fourteen to fifteen per cent of albuminoids. It is richer when snitable for boiling than when ripe. After the boiling period, the starch, fat, woody fibre, etc., increase rapidly, while the nitrogen compounds fall behind.

Cocklebur.—Will it Poison Swine ?

Many cases of sudden death in swine have been ascribed to the Cocklebur, and numerous inquiries have been made in recent correspondence as to its poisonous character. The probabilities are against Cocklebur being a poisonous plant; the family to which it belongs, the Composite, while the largest among flowering plants, is singularly free from deleterious species, and when we consider their total number, about ten thousand, there are very few that possess any marked active qualities. But it is not necessary that a plant should be poisonous to be injurious to animals. We have an example in Hungarian grass, which has caused the death of horses. The seed-head bears numerous small, roughly barbed bristles. When the grass is cut at the proper time, these bristles are harmless. When the seed is ripe the bristles are very hard and sharp,

and in the stomach and intestines of the animal, mat or felt together by the aid of their barbs, forming large balls, which obstruct the intestines and prove fatal. In these cases, death is evidently not from any poisonous quality of the hay, but is due to mechanical causes. While Cocklebur may not be poisonous, it may in a similar manner kill swine by mechanical obstructions. That it is abundantly provided with means for forming these, will be seen from the description and engravings of the plant. Besides Cocklebur, Clotbur, and Bur-weed are other common names for the *Xanthium strumarium* of botanists. It is found all the way across the country from ocean to ocean, and

Fig. 1.—UPPER PORTION OF BRANCH OF COCKLEBUR.

extends from Canada to Texas, and far southward into Mexico. The plant is also a native of the warmer parts of Europe, and it extends to the southern parts of England. It is very frequent along road-sides in rich land, and is a rough, branching annual, one to three feet high, with coarsely lobed leaves. Figure 1 shows the upper portion of a branch with its foliage. The staminate flowers are in small, globular heads at the top; the pistillate or fertile flowers are below in the

Fig. 2.—THE HOOK-BEARING BURS.

axils of the leaves, enclosed by pairs in a strong, prickly covering, called an involucre. As the seeds mature, the involucre enlarges, and when ripe, is about two-thirds of an inch long, hard, and armed with strong, hooked prickles. Figure 2 gives at the right-hand an entire bur, at the left-hand is a bur cut cross-wise, to show the two seed-like fruits, above these is one of the hooked prickles. When the burs are ripe, they readily leave the plant, and attach themselves to the coat of any passing animal. The plant is especially an-

noying to sheep-owners, as these burs become entangled in the wool. Those who have travelled in Texas and Mexico, soon make acquaintance with the Cocklebur. Horses and mules, while grazing for a single night, will have their tails clotted with these burs, and converted into a useless elub. It can be understood, that should swine eat the burs in considerable quantity, the pieces of them can, by means of the prickles, form masses which may prove fatal. Both on account of its probable danger to swine and its injury to sheep, there should be an united effort to destroy the plant. Being an annual, its extermination would not be difficult. If the plants are cut down before the seed is ripe, new ones can not appear unless the ground is re-seeded. Cut them before the seeds mature.

Instructions for Making Lawns.

ELIAS A. LONG.

There are two ways of making a lawn, the one by sodding or turfing, the other by sowing grass seeds. For small gardens the former is undoubtedly the best, while for larger areas, seedling is necessarily done, as it generally makes a good lawn, and is much cheaper, although more time is needed to bring it to perfection.

If it can be done, the ground to be put into grass ought to be allowed to settle during one or two good rains after the last grading, and then be sodded or seeded. Otherwise some slight unevenness

AN EARTH-RAMMER AND SOD-BEETLE.

may appear after thorough settling. If the rain cannot be waited for, the earth may be settled with the roller. An earth rammer may also be brought into use, and if it is found that any spots are softer than others, they should be firmed by this tool, afterwards even-up the surface as may be needed, by the use of the rake. The engraving shows an easily made earth-rammer and sod-beetle combined, that will be found useful in a garden. For firming earth, it is used mostly in a perpendicular position, striking the soil with the heaviest end; but in settling sods evenly, these are struck mostly with one of the flat sides. It may be worked out of a solid piece of five by five-inch scantling, and is usually made about four and a half feet long.

In laying sod, the surface of the ground should first be slightly loosened with the rake to make a bed for the grass roots, and if dry, sprinkled as fast as the turf is brought. The best turf is that taken from a pasture lot or roadside, that has been kept low by grazing. That where sheep have been pastured is preferred, as these animals, by their habit of biting close to the ground, destroy the coarse weeds. The better way of taking up the turf is to have the sods in long pieces, and to roll them up. In cutting the sod some gardeners use the flue, and others a board with a straight edge, in order that the cutting may be accurate. The board has this advantage, that it may be a foot wide, and then it can serve as a gauge for width without any further measuring, by cutting closely along the sides. First the cut should be made lengthwise with a sharp spade or turfing iron. Then starting at one end, one man with a sharp spade should cut the roots, so that the sod will be about an inch and a half thick, the assistant grasping the end and rolling it up, the grass side inwards, keeping on as the cutting proceeds, until a roll as large as it is convenient to handle is gathered. Where one man works alone, he may separate the sod by thrusting the spade in from the side, afterwards rolling it up. These rolls are readily transported, and quickly unrolled and laid, leaving the lawn surface with few seams, as compared with cutting in square pieces. Sodding may also be as well done by using sods that are cut about a foot or fifteen inches square. Join all edges carefully, using a large knife in cutting. As the laying proceeds, if some portions of the turf happen to be a little thinner than others, soil should be worked underneath such parts. The different pieces should all

be snugly pushed together as the work goes on. After being properly laid, all parts should be beaten with a wooden beetle, and afterwards well rolled. All of these operations are to be followed by a heavy sprinkling of water to encourage new growth. Along the line of walks, drives, and borders, the turfing should be carried a little beyond the line, as it will be, when finished, so that in dressing down the edges afterwards, the cutting will be through good, strong sod.

Where lawns are made by seeding, the work is commenced by turfing. Wherever there is a termination in the grass plat, not otherwise bounded, a strip of turf about a foot wide should be laid down for making a firm edge. Do not remove the soil quite as deep as the sod is thick, as some allowance should be made for compression in beating. When ready to sow the seed, the surface should be passed over with the rake and mellowed up a little on the top. It is a common error to use grass seed too sparingly. Use four or more bushels to the acre. Where it is known that any one sort does well, it is best to sow only that one kind. As a rule Red Top, Bent grass, or Blue grass, are generally preferred. Where it is thought best not to depend on one alone, then several kinds should be mixed. Some always sow a little White Clover with the grass seed, for the greenness it maintains in drouths, but wherever lawns are kept watered this should not be added. In sowing, the seed should be divided into two portions, half to be sown by passing over the land in one direction, and then, after lightly raking over the surface, sowing the remaining half cross-wise. Rake in the seed, or use a brush harrow, and after this let a thorough rolling be given.

As the grass starts up, and the weeds with it, the mower must be kept at work on the new lawn. The weed seed lying in the ground usually comes up quickly, and will prove annoying for a while, but if the grass was sown thickly enough, and the mowing and cutting out coarse growing weeds are attended to for the first season or two, the lawn will come out all right in the end.

The Farmer's Grindstone.

R. G. NEWTON, DAKOTA.

Obtain a good stone weighing about one hundred pounds, medium grit, and a set of friction rollers. For the frame a two by eight pine joist, is as good as hard-wood. With a stone thirty inches across, cut two pieces thirty-eight inches long; dress them square, and cut two "gains," as in figure 1, a quarter of an inch deep and a trifle narrower than the thickness of the end pieces. The distance between the gains is about thirty-one inches. Set these pieces on edge, and fit the rollers in place. Cut the end pieces so they will drive snugly in the gains; if painted before driving together, the frame will last longer. Bore three or four holes through the side pieces at each end, and nail the parts firmly together. The four legs are made from a piece of scantling, two feet long and divided lengthwise,

Fig. 1.—SIDE PIECES.

as shown in figure 2. The stone and frame complete are seen in figures 3 and 4. The upper ends of the legs are fitted on the frame, as shown in figure 4, and bolted and nailed as in figure 3. The treadle is hung on a half inch iron rod, passing through the two legs on right side of figure 4. A piece screwed on that end of the treadle and a hole

Fig. 2.—THE LEGS.

bored through as in figure 5, will hold all the parts solid. The treadle can be connected to the small crank by a four-sixteenths inch iron rod bent as shown, the lower end being hooked into an eye in the treadle. To supply the stone with water, hang a pail or bucket over it with a faucet or plug in the side near the bottom. Use only sufficient water to keep the stone moist. A trough placed under the stone, as is sometimes seen, is a detriment to the stone, as the part standing in the water will soften

and wear away much faster than the rest; it also washes the stone of loose grit, which, if retained, will cut as fast or faster than the solid stone, and

Fig. 3.—SIDE VIEW OF GRINDSTONE.

greatly lengthen the time the stone will wear. On the left of figure 3, is shown a shelf, which may be firmly nailed to the frame with a brace underneath.

To grind a plane iron with a true bevel, rest the lower end on this shelf as shown, and place a scratch awl firmly in the shelf where the end of the iron may rest against it. A chisel or similar tool can be held on the shelf by tacking or screwing on a block of wood in place of the scratch awl.

To hang the stone on the shaft snugly, fit a piece of soft wood into the square hole in the stone; saw the ends off so it will be a trifle shorter than the thickness of the stone; draw lines with a pencil or awl from corner to corner, as shown in figure 6, and where the lines cross, place the point of the auger. Bore from both ends. Insert the shaft, and place on

Fig. 4.—END OF GRINDSTONE.

Fig. 5.

Fig. 6.

the washers and nut. If the stone does not run true, place pieces of card or paste-board between the stone and washer, on opposite sides, until it is adjusted.

To "true up" the face of a grindstone, use a piece of soft iron rod or gas pipe, about half an inch in diameter, and hold the lower end lightly, but firmly, against the stone, as shown in figure 7. Roll the iron on the rest, so as to remove a small cut at every revolution. Do this when the stone is dry. It will require some one to turn the stone steadily, as a person cannot work the treadle to advantage while "truing" the stone. Always keep the grindstone housed and in the best possible order.

Fig. 7.

THE DUST BATH.—Every poultry house should have its dust box, in which the fowls can take a daily dust bath. This is essential to the well-being of the fowls. They will otherwise almost surely become infested with vermin. Fowls running at large provide themselves with the necessary dust in their covering of feathers, especially if they have access to a much travelled roadway. Lay in a supply of fine dust now, to be used when the fowls are confined to the house with only a restricted yard.

Walks and Talks on the Farm.

New Series.—No. 3.

If you do not know what else to sow, sow rye. Sow it at any time in August, September or October. Last year, as fast as we dug the potatoes, we plowed the land and sowed rye. It is a good crop to seed with. Sow Timothy, or Herds' grass, in the fall, and the clover in the spring. But if you do not want to seed down the land, it will do no harm to sow rye, and that whether you want to pasture it in the spring, mow it for green fodder, cure it for hay, or let it ripen its seed. The expense is little. Many farmers only sow a bushel of seed to the acre. I prefer to sow two bushels. I want the crop thick enough to smother the weeds.

I was on Mr. Loder's farm the other day. He has a silo, and soils his milch cows in summer. His first crop ready to cut in the spring is rye. As fast as the land is cleared of the rye, he plows it and drills in Southern corn in rows three feet apart. He keeps the crop clean with the horse-hoe, cuts it in the fall, and puts it into his silo. Last year the frost cut it for him, and the silo was empty. How would white mustard do for ensilage?

In my experience, the trouble with any second crop is to get the land moist and mellow. The first crop draws out all the moisture, and leaves the land hard to plow, and still harder to reduce into a mellow condition. Of course much depends upon the character of the land. Light sand and mucky soil are easily worked, and it is not difficult to grow one crop immediately after another.—“You mean,” said the Deacon, “it is not difficult to get the land into good shape. You recollect planting corn after a crop of early cabbage plants. You got the land in fine condition, and though it was heavily manured in the spring for the cabbage plants, the corn was absolutely poverty stricken.”

“That's all true, Deacon,” I said, “and there is no fear of my forgetting it. It is one of the many agricultural facts that need explanation. There was manure enough, but it was not sufficiently available. The land perhaps lacked moisture. Moisture and shade would have favored nitrification of the organic matter of the soil and manure. A slight dressing of Nitrate of Soda and Superphosphate, might have given me a good crop.”

“All your men,” said the Deacon, “seem to have great faith in Nitrate of Soda.”

“Probably,” said I, “it will not pay a ordinary farm crops—certainly not on corn, oats and wheat, at the present prices—but the market gardener, seed grower, or nurseryman, who does not use it occasionally as an auxiliary, is not living up to his privileges. I am satisfied that it is a mistake to suppose that true science will not greatly aid the farmer, the fruit grower, the florist, the gardener and the nurseryman.

Farmers have to stand a good deal of abuse. It is said we use small barrels for packing our apples and potatoes. I do not think it was the farmers who introduced them, but rather the dealers and shippers. I know I stoutly opposed their use from the start. The farmer gets no advantage from them. The interest of the producer and consumer, sooner or later, is identical, and for my part, I should be glad to see all our barrels of one uniform size. Then we are accused of putting good apples on the top and bottom of the barrel, and poor ones in the middle. There is some truth in this. But it is not entirely the fault of the fruit grower. The apple buyers come and look at our crop while growing. One year I sold my crop to a dealer, and he was angry because I put just as good apples in the middle of the barrel, as on the top and bottom. “Why,” said he, “I could take those same apples and make them worth half a dollar a barrel more.” And he told me how to do it: “Pick your apples carefully. Do not sort them while picking. Place all the fruit from a dozen or more trees in a long heap. If there is danger of rain, cover them with bags or canvas. When you commence to barrel, set the barrels alongside of the heap, take out the heads and lay them with the top hoop opposite the

barrels, so that they will not get mixed. You want to run three or four barrels at the same time. If the ground is soft, lay a wide plank alongside the heap for the barrels to stand on. You should have baskets that will go inside the barrel and turn over. Never pour apples into the barrel. Tell the men they must be even more careful than in handling eggs, and what is more important, see to it that they are careful. Do not leave them a moment.

“Pick out a basketful of the handsomest apples—those that are of good size, good shape, smooth, and high-colored, especially at the stem end. Place these apples with the stems down at the bottom of the barrel. Commence at the outside, and place a ring of apples all round the bottom of the barrel, and then another ring, until the bottom is compactly covered, as shown in the engraving. The second layer of apples should also be selected with care, and so placed in the barrel that they will look well when examined. Fill up the barrel with apples, and as each basket is emptied into the barrel, if you see any handsome apples, take them out and place them in a basket for ‘liners.’

“Let the men who are picking up the apples at the heap, have a basket into which they can place handsome apples for liners, and after you are fairly started, and the first barrel is nearly full, top it off with handsome apples selected from the middle of the barrels that are being filled. Formerly buyers only examined the lined end or bottom of the barrel, but now they want to see both ends of the barrel. When the barrel is one-third full, or as

APPLES ARRANGED IN THE BARREL.

soon as there is no danger of disturbing the liners at the bottom, give it a shake, and then afterwards, as each basketful is emptied in, give the barrel a shake, and when you see a good apple, pick it out for the top or bottom. On the other hand, as you approach the top, select out any light-colored or inferior apple you happen to see, and place it in the barrel alongside, that is about half full.

“Be sure and shake the barrels until the apples are as compact as possible. This is very important. Be careful to place the two top layers of apples in good style, and then lay on the head and press it down into its place. You do not want the barrels so full that the apples will be mashed in pressing, but they must be so full that when headed up the apples will not move in the barrel.”

I am not apologizing for men who place poor, wormy fruit in the middle of the barrel. I only say that dealers like to have fruit packed as above described. At any rate, it is a fact that I was held up to ridicule by a large and experienced dealer because I put just as good apples in the center as on the top and bottom of the barrel. Farmers are not dishonest, and they are not going to lose the foreign market.

“It won't pay this year,” said the Deacon, “to put poor apples into a barrel. Better sell them to the vinegar and evaporating establishments.”—“It never pays,” says I, “to barrel poor apples. It might pay very handsomely to carefully select the apples, and put only the very best into the barrel—top, bottom, and middle alike. But in such a case, as a rule, you must sell to the consumers and not to the dealers. The dealer will seldom pay more than his regular price. Probably the men he is buying for, limit him to a certain figure. A New York fruit man once came to me and said, he wanted a few barrels of choice apples, selected with the greatest care, and wrapped in tissue paper. He wanted them for a large dry-goods house, who sent them as Christmas presents to some of their manufacturing friends and correspondents abroad. For some years before his death, I used to furnish my old friend, Mr. Vick, Northern Spy apples for the same purpose, and I have heard him tell how much such apples would have brought on the other side if they were for sale. I am confident that if our apples get to Europe in poor condition, it is not the fault of farmers. At any rate, the remedy is in the hands of the exporters and dealers. Let

the exporters tell us what they want, and we will meet their wishes. In the meantime let them stop abusing the farmer. If they want larger barrels they can have them; if they want good apples, carefully picked and packed, they can have them.

When people get tired of building telegraph lines and railroads, ditching and underdraining will have a little chance of securing the necessary capital and labor. A low rate of interest ought to enhance the value of improved farms.

The Deacon thinks many farmers keep too many horses. I do not think so. But it is certainly a mistake to let horses lie idle. After winter wheat is sown, the horses on many farms do not earn their feed. We are busy with fall work, and as there is no plowing that must be done, we prefer to let the horses stand in the barn rather than spare a man to drive them. It is a mistake. There is nothing pays so well as fall plowing, and getting land ready for spring sowing. The longer I live the more I am impressed with this fact. I say nothing on the disputed question in regard to breaking up sod-land in the autumn. It is possible, as some claim, that there is a loss from drainage. But if any one will plow my land in the fall, I will run the risk! But what I have specially in mind is, land not occupied with any crop—corn-land, potato-land, bean-land, stubble-land, and weed-land. Stiek in the plow if you can spare the time; if not, harrow, or cultivate. Better still, do both. Light, sandy land, plowed and prepared in the autumn, can be sown in the spring without plowing. Heavy land, if plowed and worked in the fall, may need plowing again in the spring, but the work will be easier and the land better. Keep the horses busy until snow flies. But the earlier the work is done, the better. One plowing while the land is dry, is worth two plowings when it is wet.

It is discouraging work, plowing, harrowing, rolling, sowing, planting, and cultivating hard, clayey land, that needs underdraining. It will pay well to underdrain it. Such farms as John Johnston's and Robert J. Swan's, and many others, were originally almost worthless, and are now exceedingly productive and profitable. Go where you will, you see more or less of such hard and unproductive land on many farms. The remedy is underdraining. But if this cannot be done, seed it down to grass. It does not pay to work it.

One of the best implements for killing weeds is the mowing machine. If the land is so rough you are afraid to risk a new machine, take an old one.

Said the Doctor the other day, “Did you ever think what a comparatively small area of land there is in the world embraced in the grass belt? At first sight it seems strange, that the farmer who can grow grass should grow anything else.” The Deacon smiled at this remark, but remained silent for some time. “Well,” he said at length, “we do grow a good many weeds.”—“Yes,” replied the Doctor, “and it requires more plant-food to produce these coarse, rampant weeds, than to produce fine, nutritious grass. And aside from the difference in dollars and cents, what a beautiful country we should have if this rough, weedy land was seeded down with grass, and cut once or twice every year with the mowing machine. It would be an easy matter to scatter a little Timothy, or any other good grass seed on all the waste places in August and September, and this with the use of the mowing machine, and the scythe, or brush hook would greatly change the aspect of the country. I do not know how much seed it would require to the acre (‘about a peck,’ said the Deacon), but I know the seed is cheap, and it cannot but pay ten times over. I suppose it is not necessary to sow grain with the grass seed?”

“No,” said I, “but when you want to seed down land with Timothy alone, it is well to sow plenty of seed. As the Deacon says, a peck to the acre is enough, but half a bushel will do no harm. On moist, mucky land, I have had a grand crop of Timothy hay the next year, from seeding alone in September—the earlier the better.”—“A little rye,” said the Deacon, “say half a bushel to the

acre, does no harm, unless you want to sell the hay. For your own use, especially if the hay is chaffed and mixed with meal, or mill-feed, rye and Timothy, cut before the rye gets ripe, make excellent and economical fodder for horses."

"There is one thing," said the Doctor, "that our farmers are doing that is highly to be commended. Our roads are many of them four rods wide. Formerly when we did not know where else to put stones, brush, and weeds, they were dumped into the road. Now the practice is becoming quite general of turnpiking the road in the centre, drawing on more or less gravel, and keeping it smooth by the use of the road-scraper, and plowing and sowing the remaining land on each side."

I have seen the best of wheat growing close up to the traveled road, and the best of clover and grass the next year. It has a remarkably neat and thrifty appearance, adds greatly to the beauty of the country through which the roads run, and to the actual and selling value of the farms.

A Sliding Measuring-Rod.

The engraving represents a convenient device for measuring in places where a long pole can not be used. To make this measure, take a three-inch strip of straight-grained timber (hard-wood is best), and out of the center cut a slot with a rip-saw, an inch wide, running from the top, to within six

A MEASURING ROD.

inches of the bottom. Saw out a "tongue" to fit snugly into this slot, and mark the scale of inches and feet upon one side. If a twelve-foot pole is desired, make the piece containing the slot six and one-half feet long, and the tongue five and one-half feet. To hold the tongue in place, and keep the sides from separating, narrow zinc strips are fastened around the whole, but not so tightly as to prevent the tongue from working freely. These strips are marked *a*, *a*, in the cut, *b* representing a small thumb-screw to be turned against and hold the tongue, after it has been placed at the proper height. As the length of the slot-piece is known, the measurement of an object is obtained by adding the slot-piece length to the number of feet and inches indicated by the scale on the tongue at the point where it enters the slot.

Autumn Care of Meadow Land.

Meadows should not be closely grazed at any time, and especially not in the fall. They need to have fertilizing materials added to instead of taken from the soil. Young animals are much more injurious than mature ones, while full-grown stock that are being fattened, and are fed rich grain rations, may by their droppings add materially to the fertility of the soil. Young-growing stock withhold a large share of the potash, phosphoric acid, and nitrogen of the food to build up their bodies, leaving the manure comparatively poor. On the other hand mature fattening animals need very little of these three chief elements of soil fertility. Aside from the loss of plant-food, the close feeding of stock on meadow land does mechanical damage. If the soil is soft, the feet of the animals injure it, and the close grazing pulls much of the grass up by the roots. Meadows, like winter grains, are injured by freezing and thawing, and the plants need to be in a vigorous condition in late fall, with a good growth of after-math for protection from the frosts, winds, etc. Well-rotted manure applied to the meadows as a top-dressing, will strengthen the plants and insure a fine crop the next season. This application is best when made soon after the hay is removed. Later in the season much of the soluble material is washed out of the soil by the fall rains. Quick-acting manures should be used in the growing season, otherwise loss is sustained. Take good care of the meadows, for they suffer greatly if abused. They are easily and often injured by animals in late autumn.

Bee Notes for September.

W. Z. HUTCHINSON.

If a few bees are seen entering the hive, it should be examined. Perhaps from some cause the colony is queenless; and unless proper attention be given, its stores will soon fall a prey to the bee-moths' larvæ, or to robbers. In localities where buckwheat or other field forage is abundant, bees sometimes swarm in the early part of September. By hiving such swarms, giving them sheets of comb foundation or empty combs, and perhaps supplying them with a frame or two of brood, they will usually build up fair colonies by winter, and will frequently be found among the best the succeeding year. Honey is a luxury. Many people do not go to the grocer expressly to buy honey, and only purchase it when seen. Comb honey is usually placed in a side glass case; and extracted honey too frequently is kept out of sight. Bee-keepers would do well to furnish each grocer with a neat stand, upon which to expose his extracted honey for sale. Nearly all extracted honey will soon begin to crystallize or "candy," and it should be placed in vessels in which it is to be stored. The writer markets his honey in small tin pails, varying in size from one pint to two quarts. These are filled with honey just as it begins to crystallize, and when solid, the pails have neat labels affixed, stating that crystallization is a good test of purity, and that a gentle heat will soon liquify the honey.

The present month is an excellent time to change the stock of bees. The main honey harvest is over, and if the colony remains queenless a few days, the loss is not great. The best queens are reared during the height of the honey season, and can be bought very cheaply. Purchase queens of the nearest reliable breeders, as long journeys by mail often exhaust them of their vitality to an injurious extent. Queens used to be vigorous.

FALL FEEDING.—In the Middle States fall-feeding should usually be finished by October 1st, in order that the food may be ripened and sealed before cold weather comes. Granulated sugar, or "confectioners' A" are the least likely to be adulterated. The best way to secure pure sugar is through some reliable candy manufacturer. To prepare the syrup, add one quart of water to four pounds of sugar. Heat the mixture to boiling, and skim. Let the feeding be done as rapidly as possible, so that the bees will not be thereby stimulated to undue breeding.

A BEE-FEEDER.—An excellent bee-feeder is shown in the engraving. The feeder is as large as the top of the hive. The sides are four inches high, and made of well-seasoned half-inch pine boards. The bottom of the feeder is one inch

A BEE-FEEDER.

in thickness. A division-board, *c*, is fitted within the feeder about two inches from the right side, and extends upwards from the bottom board (to which it is joined), to within three-eighths inch of the top. The heads of the nails holding this board in place can be easily seen. The bees crawl up in the space between this division-board and the top of the feeder; then over the top of the division-board, and pass into the apartment containing the food. Another division-board, *e*, extends from the top of the feeder to within one-eighth inch of the bottom-board. When the feeder

is in position upon the hive, the cover is moved back until its edge is even with the top of the division-board, *e*, when the food is poured into the space between the division-board and the board forming the outside of the feeder. The food passes under the division-board, and rises in the centre apartment of the feeder to which the bees have access. After the feeder is filled, the cover is drawn back to its original position. To give the bees a foothold, the center apartment is filled with little slats of wood one-fourth inch thick, and wide enough to reach within one-fourth inch of the bottom. These slats, the upper edges of which can be seen at *f*, are held in position by two rows of small wooden posts slipped down between them. These posts, the tops of which can be seen at *g*, *g*, are three-eighths-inch thick, and rest upon the bottom. The joints of the feeder are made water-tight by painting the edges of the boards with white lead, before nailing them together. With this feeder there is no escape of heat; no daubing of bees; no exposure of the food to incite robbing; and no bees escape from the colony when filling the feeder. The bees can take the food very rapidly, and a large amount of it may be given at one feeding.

Prepare for the Fairs.

Go to your fair, whether it be the State Fair, or that of the County, and by all means exhibit something. It will be safe for those, who propose to exhibit fruits and vegetables at the coming fairs, to assume that no provision will be made for them and to prepare before-hand. Common store boxes, such as may be had at a very small cost, can each be converted into two or three trays or flats. These, however rough they may be, by lining with cheap, white paper, will serve for the display of fruits. If lined merely with moss or freshly cut grass, they will serve for showing vegetables. If the premium schedule calls for a bushel or half bushel of potatoes or of apples, etc., these may be exhibited in receptacles made by cutting a half-barrel in two, and lining each tub thus made with white paper. Help decorate the "Floral Hall," the place in which the products of the garden are usually shown. Young evergreens are always welcome. Such trees, taken up from pastures or the edges of the woods, and set in nail-kegs with soil, will last as long as may be required, and greatly add to the general effect of the display of vegetables.

Rainfall and Distribution of our Grains.

Over ninety-two per cent of our wheat is grown where the annual rainfall is above twenty-five inches; sixty-two per cent where it is between thirty-five and fifty inches, and over twenty-eight per cent with an annual rainfall of forty to forty-five inches. The important wheat region of California has less than twenty-five inches annual rainfall, but the rains come at the most favorable time for the grain. Nearly half of all our wheat is grown where the rainfall during the growing season is not over twenty-five inches. Over sixty-five per cent of all our Indian corn grows where the spring and summer rains do not exceed twenty-eight inches, and ninety-eight per cent where it is between fifteen and thirty inches during the growing season. Corn is emphatically a hot weather plant, and will not thrive in Europe, where the summers have less bright sunshine, though the rainfall seems more favorable than in this country. Four-fifths of the national oat crop is grown where the mean annual rainfall is between thirty and forty inches, and the spring and summer rains range between fifteen and twenty-five inches. Oats like a cooler climate than corn. Barley has the widest range of climate of all cereals, and the greatest production is with an annual rainfall of fifteen to twenty inches—much less than that required by other grains. We are apt to overlook the importance of clouds when harvesting a crop, and even think rains a great inconvenience; yet without them during the growing season there would have been no golden grain.

Southdown Sheep.

The Southdown is the most popular breed of mutton sheep in the world. The mutton is most excellent, and the wool of a quality in demand by the manufacturers of cloth. The growth of the animals is rapid, so that they may be early fattened either as lambs or mutton sheep, and besides they are quiet, hornless, hardy, and prolific. Other breeds surpass them in size, and quantity of wool, none in perfection of form, or in excellence of flesh. So true is this, that no butcher who has cut well-fed Southdown mutton will fail to recognize the blood even though in the second or third cross. The excellence of form in the Southdown is seen in its remarkable symmetry and squareness, in its length of body, breadth of loin, the broad hind-quarters, high at the rump, lowness in the twist, and in the deep, thick hams. The brisket should be both prominent and deep, the fore-legs straight and wide apart, the belly-line level, and the flank as low as possible. The heads of the Southdown are small, of a gray, or brownish-gray color, well woolled between the eyes and across the poll. The wool, which should cover the belly, extends to the knees and hocks, and the legs are covered with dark, straight hair. They are naturally fine, but should be flat and not too delicate.

The Southdown belongs to the class of middle-wool sheep. The wool is of medium length and fineness, close and even, and forms a fine coat and protection against changes of weather and climate. It is no doubt owing in part to this that the Southdowns prove hardy wherever introduced. The breed has been made use of to improve other

England, and largely in this country. We see them, or their grades in the market, with their legs left with the skin on, to indicate the breed, and connoisseurs of mutton are thus attracted to buy.

"Holstein" Cattle.—A Famous Cow.

The cattle of the Netherlands are attracting more attention from the dairy farmers of the

Ethelka gave eighty-one and one-half pounds of milk a day. These cows were neither of them four years old and with their second calves.

A breed with such possibilities, even though the average fall far below, is one upon which too great care can not be spent, with a view to both preservation of these inbred qualities, and to render them the more uniform inheritance of the race. The place in this country for the cows of this ad-

mirable breed, is in the great dairy regions, where cheese is the principal product, for notwithstanding the enormous butter yield of some "Holstein" cows, it may well be questioned whether as butter yielders they can be economically used.

We have not yet begun to test cows for their product of cheese, and though it is certain that individuals vary greatly, the popular idea is that the richness of milk in casein (cheese), is much less variable than its richness in butter. Great results, whether of milk or butter, cannot be produced without abundant feed, and as a

rule large breeds of cattle or horses are best adapted to highly fertile sections, where from their very birth a healthful abundance prevails.

The grand cow, "Crown Jewel" (2690), whose portrait we reproduce from a lithograph, was imported in September, 1882, as a five-year-old. She is now seven, and presumably in her prime. She is of the "blue blood" of Holland, at home bearing the name *Boofje*, and in the Netherlands herd-book is number 592. She won the Sweep-stakes prize as the best cow of any age or breed at the Wageningen Show, and is said to have yielded before her importation to this country eighty-two and one-third pounds of milk in one day. The voyage

THE HOLSTEIN COW "CROWN JEWEL."

country than any other breed. For many years they have been carefully bred, with an aim to produce large quantities of milk. Doubtless the quality of the milk has been less an object with the breeders of Holland; but when well-fed cows give enormous quantities of milk, and the milk can be disposed of as such, the profit is almost invariably greater to the producer than if the quality were better and the quantity less. Besides, milk of low quality is poor in fat, but not necessarily poor in cheese substance. The districts whence they come, have always been famous for both cheese and butter, so that without further evidence our farmers might safely assume, that the milk was really rich

A GROUP OF CELEBRATED SOUTHDOWN RAMS.

Drawn and Engraved for the American Agriculturist.

"Down" sheep, and these by offering lambs of larger size, which are quicker fit for market, may have in some cases advantage over the pure Southdown—the first improved, and by far the best of the breeds of the Downs. It would, however, be a mistake to suppose that the breeders of Southdowns in England are chiefly confined to the Counties of Kent and Surry, and that vicinity whence they sprung. They are now bred in all parts of

in both butter and cheese. But we have other facts. The famous cow Mercedes, now dead, was the especial rival of the Jersey cow Mary Anne of St. Lambert, for the honor of being the greatest butter cow in the world, and the no less worthy and scarcely less famous heifer Jamaica, is credited as giving one hundred and three and one-quarter pounds of milk a day, and in a week as yielding twenty-six pounds three ounces of butter, while

across the Atlantic is a severe tax upon the constitution of any cow, and a year's rest is always needed before she gets fairly over it. During this year, imported cows must not only recuperate from the fatigues and bruises of the voyage, but encounter a new and changeable climate, of much greater severity of both heat and cold, than the one in which they were bred, and to it they must become not only accustomed, but acclimated. It

is therefore very remarkable, that the first season in this country she should have so far regained her health and vigor, as to have produced in one day eighty-one pounds thirteen ounces of milk, in one month two thousand one hundred and nineteen pounds five ounces, and in one year, terminating in May last, fourteen thousand seven hundred and twenty-four pounds one ounce. This, it will be noticed, is equivalent to over seventy pounds of milk a day for the month, or thirty-four quarts, and to over forty pounds on an average, which is nearly twenty quarts, daily, throughout the year. This is certainly a most wonderful record. Such a quantity of milk, if of only moderate quality, must yield a good deal of butter, so we need not be surprised to learn, that she made nineteen pounds nine ounces of butter in one week, of excellent quality, texture, and color.

Apples for Exportation.—Small Barrels.

In his "Walks and Talks on the Farm" this month, Mr. Harris discusses the subject of packing apples. The dealers in this city have now organized a movement, the object of which is to induce the apple-growers of Western New York to pack their apples in flour barrels. For many years past, the legal apple barrel in this State is made to hold not less than one hundred quarts of wheat. This legal barrel is what the dealers now derisively term the "pony barrel," to distinguish it from the flour barrel. The latter holds about one hundred and twelve quarts, or one-seventh more apples than the legal barrel. In other words, if the fruit in the pony barrel is worth one dollar and forty cents, that in the flour barrel is worth one dollar and sixty cents.

A flour barrel is made to hold twenty-eight stone of flour, or one hundred and ninety-six pounds. Neither the millers, the dealers, nor the consumers ask to have it made to hold two hundred pounds. No one asks for a change. Taking it for granted, therefore, that the flour barrel size is to be the standard barrel, the apple dealers ask that apples be packed in barrels of this size. The dealers say, that the apple-growers in New England and in the Western States pack their fruit in flour barrels. And when they come to sell the apples, their customers naturally prefer the larger sized barrels. Furthermore they claim, that the charges for freight, cartage, storage, handling, and commission, are as much on the smaller as on the larger barrel, and these charges, especially on apples sent to Europe, are very high. We believe that all the apple-growers are perfectly willing to use the flour barrel size, provided the dealers will pay a proportionately increased price. Hitherto, when a farmer packed apples in a flour barrel, the dealers would not pay a cent more for them than for the smaller barrel. This the dealers themselves admit. They admit, furthermore, that if nine-tenths of the farmers in the vicinity of such shipping points as Lockport, Broekport, and Speuceport, should pack their apples in flour barrels, it is possible that transient buyers, who want only a few car-loads for such places as Harrisburgh, Pittsbnrgh, or Bradford, might come in and pay nearly or quite as much for the smaller as for the larger barrels of fruit. They have orders to buy a certain number of barrels at a given price—and a barrel is a barrel. Confessedly, therefore, the New York dealers cannot control this matter. And it will be unwise and unjust on their part, to hastily and arbitrarily endeavor to force farmers to make the change.

The winter apples grown in the vicinity of the Lakes and on the limestone soils of Western New York, are unsurpassed in quality. They keep well, and are admirably adapted for exportation. It is asserted, however, that these apples cannot be sold abroad, because they are carelessly and dishonestly packed in small barrels. We believe that this statement is exaggerated. It is true, that many of our apples reach the foreign market in bad condition. But the fault is not wholly due to the farmer. When apples are scarce and the de-

mand likely to be brisk, the dealers get excited and take anything that is offered them. The careful, skillful, and honorable apple-grower gets no more for his fruit than his neighbor. The buyer gets his commission, and the apples are hurried forward to New York. To ship such apples as these, indiscriminately, to Europe is folly. To carelessly and hurriedly place thousands of barrels in a close, warm, unventilated steamer, to face the storms of the Atlantic, and expect them to keep well and sell well, can result only in disappointment and loss. For the dealers, smarting under their losses, to turn round and abuse the farmers is not unnatural, though it is very unjust.

The dealers and farmers must work amicably together in effecting a reform. The farmers have got good apples this year, and are able and willing to pack them in the best manner. It is not the size of the barrel that injures the reputation of apples abroad. It is the want of proper care in selecting and packing, and handling the fruit, and in securing cold, dry, well-ventilated room on board the steamer. Apples should receive as much care in this respect as dead meat. The subject is one well worthy the attention of steamship companies.

The Influence of Pollen.

ANDREW S. FULLER.

The effect of pollen upon the fruit and seeds of plants is a subject that has frequently engaged the attention of both practical and scientific horticulturists during the past score or two of years. All admit that pollen is an important factor in the production of seed. Furthermore, if there is seed, there must be some other organ present to support it—a fruit-stalk; an envelope to enclose it, as in the apple, pear, cherry, and similar fruits, or something to rest upon as in the strawberry, raspberry, and blackberry. Consequently we must admit that the influence of the pollen does necessarily extend beyond what we term the fruit or even the seed. Quite recently this subject has come up anew, and interesting discussions have followed at several meetings of horticulturists as well as in the columns of various agricultural and horticultural journals. Mr. J. T. Lovett, a successful cultivator of small fruits, claims that the influence of the pollen not only extends to the seed in the strawberry, but also has a decided effect in fixing the size, form, texture, and flavor of the fruit. While those who have given this subject close attention will agree to this, there are others who still doubt, even if they do not openly deny that the influence of the pollen extends as far as claimed. At the last meeting of the American Pomological Society this question was discussed, and a number of our leading strawberry-growers stated that the Manchester, which is a pistillate variety, was notably effected by the pollen-bearing variety employed for fertilization. The Secretary, Professor Beal, of Michigan, said at the close of the discussion: "This is an exceedingly interesting topic. If the results are as claimed by the former speakers, they are indeed wonderful. The edible portion of the strawberry is not a true fruit in the botanical sense, but a large torus or receptacle, which is the tip end of the flower stem, very much enlarged." We conclude that Professor Beal doubts the truth of what has been claimed for the influence of the pollen in the strawberry. We find the same influence exists in melons, squashes, cucumbers, and similar fruits, and often to such an extent that a choice and high-flavored variety is almost ruined by being planted near an inferior one. A more striking and familiar example of the influence of pollen is that of sweet corn fertilized by the pollen of field corn. If a yellow variety of field corn is planted near any variety of sweet corn, and both come into bloom at the same time, there will be yellow kernels interspersed among the grains of the sweet, and the flavor of these will be as distinct as their color. The influence of the pollen in this case, not only extends to size, color, texture, and flavor, but often still further, for the coloring matter will usually be seen in the cob. It will be the same with two

white varieties, but the effect is more readily observed when one variety is either red or yellow.

A quarter of a century ago, when the Hovey was our best and most valuable pistillate strawberry, we conducted a series of experiments for the purpose of determining the influence of pollen on its fruit, but at that time there were so few persons making small fruits a specialty, that a man who attempted to talk of "influence of pollen" on a strawberry, would find that he had a small audience and not a very attentive one. But when writing the "Small Fruit Culturist," we inserted an epitome of the results of the investigations which appears to have been overlooked by most fellow-laborers in the same field, and we refer to them now, even at the risk of being thought egotistical. In the first Edition, 1867, page 44, we said: "But without presuming to advance a theory on the subject, we would suggest whether it is not possible that variations may have been made on growing plants, by the influence of the pollen from different varieties. It is generally supposed that no effect is produced except on the seeds, but as it is most conclusively proved in animal physiology that the female retains the effect of impregnation in her system for years, may not the same be true of plants, and the admixture or deterioration of one, and the improvement of another kind growing in close proximity, be caused by the absorption of qualities, each from the other. If the effect of the pollen reaches no further than the seed, why is not the fruit (receptacle) produced without them. But we find that wherever the pistils are not fertilized, the receptacle also fails, or if a portion only is supplied with pollen, then the receptacle is deformed in proportion. Remove one, two, or more pistils before they are fertilized, and the berry, just at that point fails to enlarge or come to maturity. No seed, no berry, is the rule."

A Liquid Manure Cart.

A large part of the fertilizing elements of liquid manure go to waste, without provision is made for storing it and applying it to the soil. A brick-walled cistern holding several thousand gallons, can be built for about fifty dollars, and this will secure a constant supply of the best and quickest acting plant food. A cheap and substantial cart for spreading the liquid manure upon the land, is easily made. The box should be water-tight, provided with two tail-boards. The outer one has several holes bored in it, through which the liquid passes when the inner board is raised for a short distance. It is easy to make a water-tight box out of tongued and grooved stuff, fitted together with paint or tar. The box is hung upon a bent iron axle, to bring it near the ground. Persons with large lawns may keep them luxuriant during mid-summer drouths, by using such a cart. Liquid manure produces its good effects upon vegetation at once, and needs therefore to be applied frequently and in small quantities. This is especially true if the soil has an open texture without retentive power.

ALL THE EGGS IN ONE BASKET.—We do not believe in it. The eggs may all be of excellent quality, and the basket strong and large enough to hold them, and yet we think it unwise to risk them all at once. There are many chances which a farmer must take, but he is rarely warranted in hazarding his present comforts in the hope of great gains. A man may invest all his capital in hops or cranberries, or some other special crop, and—lose. He may clog all the machinery of his farm operations, by going largely into grape-growing, when he might better have kept to his wheat. Farmers have been sold out by the sheriff because the horses possessed too much speed, and the race-track had greater fascinations than the corn-field. Some men run all to cider, have a mill to make it, and that is all they make. Others raise only hay, and sell it off the farm. Their eggs are all in one basket. Mixed husbandry, and not specialties, for American farmers wins in the long run,

A New Cherry.

Mr. James Dougall, one of our subscribers living in Ontario, Canada, sends us specimens of a new seedling cherry named The Dougall, in honor of the raiser. It is a seedling of the Early Purple Guigne, a variety well known to fruit-growers as an early and profitable cherry. The fruit of The Dougall is ripe about a week before that of its parent, and is larger and finer flavored. The tree is noted for its hardiness and vigor of growth, and as being a most abundant bearer. The specimens sent us show its great fruitfulness, and also the large size and vigor of its foliage. The engraving, from a photograph, shows the cherry of its real size. The fruit is of the darkest purple-color, almost black, with a remarkably juicy flesh of great richness. We accidentally discovered a quality of the fruit for which the raiser makes no claim. It is a remarkable keeper. A number of loose cherries were, by chance, left in the box, and when discovered a week or more after their arrival, save a slight shrivelling of the skin, they were unchanged. There were no indications of decay. We hope The Dougall may retain the good qualities shown by the original tree. The "Windsor," another of Mr. D.'s seedlings, has already received the attention of fruit-growers. We are glad to see a renewed interest in the cherry, which of late years has been much neglected by fruit growers.

A NEW EARLY CHERRY—"THE DOUGALL."

Wagon Shed and Tool House.

Every farmer should provide shelter for his wagons and farm tools. The engraving shows a combined wagon shed and tool house, so constructed that a wagon can be drawn under at one end, and out at the other. The shed should be long enough to leave the door into the tool house free, when the wagon is housed. A place over the shed is convenient for storing many small articles. The location of the door enables one to unload articles into the tool house from the rear of the wagon. If it

A WAGON SHED AND TOOL HOUSE.

is desired to economize space, the wagon shed may be in the roadway, and the fence joined to the house on each side, as shown in the engraving given above. In this case, there should also be a door opening into the tool house from the yard.

A SLED FOR DRAWING CORN-SHOCKS.—A sled suitable for removing corn-shocks from the field, is

made of two hard-wood planks, fourteen or sixteen feet long, rounded at one end and joined by three stout cross-pieces. Short standards should be placed at both ends of the sled, to hold the corn in place. The two runners may be separated four or

five feet, according to the length of the stalks. When corn is to be thus removed, the shocks should be made smaller than usual. After the corn has been curing a week or more, the team with the sled is driven alongside the shocks, when they are pushed over upon the sled until it is filled. The corn is easily set up again in another field or in the barn, and the corn ground is ready for the plow.

Care of the Work Team.

A poor work team makes farm operations more costly. Grooming is essential, as it gives rest to tired muscles. It is second only to proper food. It has been said: "A good grooming is worth four quarts of oats." Feed liberally, but do not over-feed. Feed regularly, and see that the team has its breakfast, dinner, and supper, before you have your own. It is poor policy to give horses no grain until they are about to do some hard job, or a season's hard work. Over-feeding with grain or grass, causes derangement of the digestion. Imperfect digestion means impaired usefulness in the long run. A horse will do more work on oats than on corn. Corn will prepare a horse for labor, but oats make a better ration during hard work. Oil and starch in corn make it an undesirable summer food; it is heating. Old hay, cut and mixed with bran or a little meal, makes a good work ration, if old hay is not plenty, feed newly cured clover or timothy. Give an occasional feed of roots, apples, and the like; they afford a variety and help digestion.

If at all possible, let the team during hard summer work drink once in the forenoon and once in the afternoon, besides at their regular meals. Judge them somewhat by yourself. See that the breast and shoulders do not chafe. To prevent it, take care to have well-fitting collars, and bathe the shoulders with cool water on returning from the field.

Sericulture in California.

Silk culture has been gaining surely and steadily in the confidence of our people for several years, and is evidently to be one of the leading industries of the future. Like most enterprises, it was begun by a few people of ability, but the greater number were over-sanguine parties, without any experience, who expected to reap a fortune in a short time. The rearing of silk-worms was begun in California about 1860, and soon after the industry grew rapidly. The best cocoons were first produced in Santa Clara County. Many persons not understanding sericulture, but intent on quantity rather than quality of product, placed millions of cocoons on the market, which were almost worthless, and wholly unfit for reeling. This done, a reaction began. It proved well nigh fatal to a project which should, ere this, have furnished profitable work to thousands of ladies and youth, who are now almost without employment. Even with so favorable an inauguration, the enterprise rested in the hands of only a faithful few, who, for several years, did little more than hold their own. Within the past few years silk culture has received a new impetus, owing in a large part to the enterprise and perseverance of the ladies. The industry is now under the fostering care of the

Board of Sericulture, consisting of nine members, five of whom are ladies. The rearing of cocoons and cultivating the mulberry are only in their infancy.

Drain Tiles for Blanching Celery.

Nothing is superior to drain tiles for blanching celery. The plants are hilled up as shown at *a*, in the engraving, and the tiles placed over them. Wrap a piece of stiff pasteboard around the plant, pressing the leaves together closely. Slip on the tile, and press the lower end into the soil as shown at *b*. Draw out the paste-board through the opening at the top. By this method celery can be grown in rows two feet or less apart, as only a little soil is required for earthing up. The leaves will

TILES FOR BLANCHING CELERY.

generally fill the opening at the top of the tile sufficiently close to exclude light from the stalks.

Last season our celery came out of the tiles clean, white, and tender, the stalks being crisp and solid, while that of a neighbor, whose celery was earthed up in the ordinary way, rotted considerably before it was blanched. The economy of space alone will pay for the tiles in two years, to say nothing of the great saving in labor. If the tiles are carefully stored, they will last many years. F. G.

Salt-Water Farming.

One day this season we were strolling on the beach which extends along the east end of Long Island. A gray haze hung upon the great Atlantic,

"THERE SHE BLOWS!"

whose surges broke at our feet, and the sand-hills which shut out the shore-ward view fairly blazed in the sun. The arbors built for the shelter of the summer visitors, who make the beaches fashionable for a portion of the year, were dry and brown. There were some boats drawn far up on the sand, but no sign of human life was in view save what we provided in our solitary person tramping along on the wet beach, within the wash of the tide. Suddenly a man appeared on one of the sand-hills, close to a stout pine trunk which was planted on its summit. The man glanced seaward, sharply and swiftly. Then he ran up the post, to which cleats were nailed, with the agility of a practical seaman. With his arm crooked about the post at the very summit, he shaded his eyes and looked at the sea again. Following the direction of his glance, we fancied we could see a dark spot far off shore. As we looked, it vanished and a white spot took its place. A shrill voice, which seemed to come from the skies, rang in our ears: "There she blows!" — When we looked at the pole, the man upon its summit had his coat off and was waving it like mad, and within ten minutes time the solitary shore was all alive. Men in their shirt-sleeves, some even bare-headed, came swarming over the sand dunes and through the breaks in them, all with oars on their shoulders. The big boats were hauled down to the water's edge; from queer little

huts like dog kennels, erected on the hillocks, harpoons, and tubs, and coils of line were brought out. Sitting under one of the arbors, we watched a whale-hunt to its end, which was the towing of the dead prize ashore, after an hour's hard battle. The whale was not brought ashore exactly at the spot from which the hunters had embarked, but some half a mile down the beach. There we found an enormous iron pot, mounted on a weather-beaten but still substantial brick furnace, on the crown of a low sand bluff. Having been beached opposite the furnace, the whale was hauled well up out of reach of the tide by powerful tackles attached to stout posts, and the captors, aided by other men and boys who had come down to watch the progress of the chase, proceeded to cut it up.

The furnace blazed all night, sending a red flare over the desolate beach, and crimsoning the cloud of heavy smoke the night wind tossed and rifted into fantastic forms. Around it the whalers gathered, relieving one another in attending to the pot and feeding the fire, and spinning yarns. A curious gathering they formed indeed. Though every one had proved himself an expert fisherman and seaman, every one was a farmer, too. They represented that singular and interesting class, of which the eastern coast of the United States and the eastern end of Long Island especially, boast so many and such splendid examples—the "salt-water farmers" as they are appropriately called.

Tillers of both land and sea, their industry makes little distinction between the elements from which they draw their double harvest. They are as much at home with their feet on the frail bottoms of their boats, as on the soil they dig, and their hands are as ready at the oar as at the plow. Brave, energetic, tirelessly diligent, they live laborious lives, and deserve all the honor that belongs to honest toilers. The readiness with which the salt-water farmers exchange their labors from shore to sea, is explained by the fact, that on our eastern coast most boys begin life with some years on-board the whalers or the fishing craft that distinguish the section. If they do not go a couple of long voyages on whalers, they make annual

comes. Formerly the salt-water farmers found considerable profit in the menhaden fishery. They seined the fish and tried them out on shares, but of late years this business has been monopolized by steamers fitted out for this purpose. There remains to the salt-water farmers, however, the capture of food fishes and also an occasional whale.

When the blue-fish or other finny prizes begin to "run," that is, when they swarm into the contiguous waters with the season, the double industry

A SALT-WATER FARMER.

begins ashore. The farmers own large boats and good seines, and lose no opportunity of using them. Their captures supply the whole neighborhood and often add materially to the comforts of the captors. While there are many fine and productive farms upon the coast, there are far more which would afford their cultivators a poor living if the ever-changing sea did not eke out the parsimonious gifts of the poor, sandy soil.

The sea not only helps the farmer's purse, but it helps the land. The refuse of the fisheries goes to

fertilize the soil. Though the competition of the steamers has destroyed the menhaden fishery on a small scale for its oil, the farmers still watch for the fish, net them and use them as manure. The abundant supply of food and other fish along our coast is one of the standard subjects of wonder and admiration with the foreigner. The deep is populated with untold millions of living creatures useful to man. Nature, which gave the farmer a comparatively sterile soil to extract a living from, seems to have added the gift of the ocean as a compensation for the shortcomings of the land. The farmer-fisheries are constructed on a simple and effective system. Whale-boats are owned in common, and their prizes are shared among their owners. Fishing boats are commonly kept on the same principle, and the owners of several farms thus share in the benefits of each successful fishery. Signal

THE MIDNIGHT HARVEST OF THE SEA.—Drawn and Engraved for the American Agriculturist.

trips with the fishing fleet, working on the farm between seasons. Such of them as eventually settle to agricultural pursuits, continue to utilize their marine accomplishments to add to their in-

posts, such as the one from which we saw the discovery of the whale, are planted at certain intervals along the shore. An announcement of a prize in sight from one of these, calls all

the salt-water farmers within hail to the work, and in some sections an extra allowance of the gains of the fishery is given as a prize to the discoverer. The discoveries are by no means always accidental. When the season in which the fish "run" is at hand, the farmers begin to find time from day to day to drop down to the beach and survey the water. An hour snatched from labor on the farm now and then, keeps one or another on the watch from dawn until dark, and it is a lucky school of fish indeed which can escape the watch, unless it is so far off shore that the impression its movement makes on the water cannot be seen. Eternal vigilance and eternal labor are the sea-farmer's lot, for the earth and sea must both be worked to make his existence comfortable. But it is a hardy life, and produces such men as one rarely sees in the restricted atmosphere of towns or on the fertile prairie, men with whom truth, frugality, and virtue are native, and whose hearts are as sound as the muscles which drive the plowshare deep, and pull the oar steadily and long.

Law For Farmers—Hiring Farm Help.

H. A. HAIGH.

The law governing the relation of master and servant is of much importance to farmers, for one of their most perplexing duties, out of which arises oftentimes most serious liabilities, is that of procuring and keeping necessary farm help.

CONTRACT OF HIRING.—The relation of master and servant always arises out of a contract, either express or implied, and the capacity of the parties to make a binding contract often determines their respective rights. Where a farmer hires a man for a definite term of service, and for a definite rate of wages, to do a specified kind of work, the contract is express. But where the farmer simply requests the man to work for him, and nothing is said about the time or pay, or where the relation of employer and employé is formed without a full and definite understanding, the contract is implied,

a definite time, both parties are bound by it until the time expires. The employer must furnish work, and the employé must labor to the end. If the master discharges the workman without legal cause before the time expires, the workman will be entitled to his wages up to the time of his dis-

It is difficult to state concisely what under all circumstances will amount to a legal cause for doing each of these things, but briefly it may be said that if the employer does not treat the workman humanely, does not employ him reasonably and in lawful pursuits, if he subjects him to perils and

THE SHORE FARMER'S HUT.—Drawn and Engraved for the American Agriculturist.

charge, and also such damages as he has suffered by being thrown out of his job. These damages will probably be the amount of the wages up to the end of the time of hiring, less what the workman has earned or might have earned at other employment. If the workman leaves without legal cause before his time is up, the great weight of authority is that he is not entitled to any compensation for the time that he has worked, though

dangers not incident to the employment for which he hired, or places him under immoral influences, or fails to furnish him suitable lodging or wholesome food, then the servant is justified in leaving. If on the other hand the servant fails to faithfully serve the master, or to obey his reasonable commands, or to treat him respectfully, or to discharge his duties honestly and with ordinary care, or if he is found not to possess the requisite skill to perform service for which he hired, then the master has legal cause for discharging him. If the servant is prevented from completing his contract by sickness, or death, or by being discharged—rightfully or otherwise—he is entitled to reasonable compensation for what he has actually done.

If the hiring is for a definite time, and the rate of wages is at so much a day, week, or month, but nothing is said about the time of payment, the wages are not due until the end of the term, unless there is a general or special custom to the contrary. When the wages are to be paid monthly or quarterly, or at other stated periods, a failure on the part of the employer to pay at such time, is good cause for the employé's leaving, and he may, if he chooses, abandon the service of the one who does not pay and recover the amount due.

IMPLIED CONTRACTS.—Where services are rendered at the request of the employer, but no promise is made by him as to what wages he will pay, the law implies a promise on his part to pay the "going" rate of wages for that kind of service, but if the work is of a kind of which no current rate exists, then the employé is entitled to what the work done is reasonably worth. If nothing is said or implied concerning the time of service either party may terminate the relation whenever he chooses without any liability to the other for any damage so caused. Where services are rendered without any request for them, but under such circumstances as lead the workman to expect pay for them, or if the person for whom the services are rendered has reason to believe that the person rendering them expects pay for them, and he allows the workman in either case to labor under that expectation, the law will imply a promise to pay what the services are reasonably worth. A man cannot continue to accept services for which pay is expected, and then avoid paying for them. Silence under those circumstances will amount to a consent to pay. A man is never obliged to pay for services that are obtruded upon him.

AT THE BOILER, AND SPINNING THE YARNS.—Drawn and Engraved for the American Agriculturist.

and its lacking terms or conditions must be supplied by law. A contract of hiring for one year or less, need not be in writing. If for more than a year, it is not binding unless in writing, and either party can terminate the agreement at pleasure.

EXPRESS CONTRACTS.—Where the hiring is for

several highly respectable Courts have held that under such circumstances he has the right to the wages due him up to the time of leaving, less the damages occasioned to his employer by his leaving. The question as to what is a legal cause for discharging and for leaving thus becomes important.

Animal Ailments.

PROFESSOR D. D. SLADE, HARVARD UNIVERSITY.

EFFECTS OF GREEN RYE ON MARES.—M. S. Griseom, San Saba Co., Texas, asks whether the feeding of green rye to mares prevents them from getting in foal, or causes them to lose their colts.—As regards the first query, we answer unhesitatingly no. To the second we say, it would only act indirectly by causing disturbance of the digestive organs, if given in large quantities, and thus interfere with the process of gestation. The chances of such a result are, however, very small. Ergoted or diseased seeds of rye are liable to produce abortion in all stock, and at any period of pregnancy, and great care should be taken to keep animals from feeding upon it.

GESTATION IN MARES.—S. H. Puckett, Ouachita Co., La.—The gestatory term of mares extends from eleven to twelve months, these two terms forming the extremes. Careful observations made in France upon five hundred and eighty-two mares, which received the horse only once (a circumstance that prevented all mistakes in the matter), showed that the shortest period of pregnancy was two hundred and eighty-seven days, and the longest period was four hundred and nineteen days, making a difference of one hundred and thirty-two days, and eighty-nine days beyond the usual period of eleven months.

STARTING AND PLUNGING OF HORSES.—J. L. Pilkington, Queens Co., N. Y., has a horse that starts violently, leaping and plunging when put into harness, and asks if some kind of bit will keep him under control.—As this habit or vice is the result of bad breaking in, together with perhaps an ugly disposition on the part of the animal, nothing but patience, firmness, and kindness can correct it. The horse should be harnessed to a vehicle, in which he can do no harm to himself or the driver, and taught, above all things, that he has nothing to fear. Proceed with the utmost patience to teach him to stand still first, and then to walk quietly. Make use of a simple, strong bit, and one which can afflict no injury to the mouth. Many horses will resist a powerful curb, that will go quietly with a plain snaffle. Coolness, patience, and kindness will overcome the fractious spirit.

CONTRACTED FOOT.—The same correspondent asks, if a shrunken or contracted foot should be considered as any detriment to a horse.—It is not unusual for one foot to be smaller than the others, either as a result of previous inflammation, or as a natural condition. A contracted foot is to be regarded with suspicion, as it is liable at any time to give rise to serious trouble. A foot that is naturally smaller than the others, need not cause any apprehension, and could only be considered as a blemish.

COLD HORNS.—H. J. Heininger, Washtenaw Co., Mich., complains that two of his cows in milk have cold horns a greater portion of the time, and yet are otherwise in good condition.—The circulation of blood in animals may naturally vary as it does in man, and we can not conceive that any coldness of the horns, when the animal is otherwise well, is any evidence of disease, or is susceptible of any treatment beyond giving abundant and nutritious food, which in turn would be the surest way of increasing the flow of milk. Leave the condition powders and turpentine for cases which need them.

SWELLING AFTER CASTRATION.—K. H. Kenny, Spokane Co., W. T.—“Well informed people” no longer make use of the “sign” in the castration of animals. Swelling of the neighboring tissues is a frequent sequence to castration in young animals, owing to imprisoned matter, or to effusion of bloody fluid. In the first case, re-open the wound with the fingers, or by a blunt instrument, and in the second place, trust to the natural absorption of fluid.

ABORTION IN COWS.—J. R. Moeller, Hall Co., Nebraska.—The causes of abortion, or premature delivery, are various and widely different in their nature. Among the most frequent are blows, slips, falls, or any violence which may destroy the fetus; improper food, or bad water, which may produce irritation of the bowels, and long and fatiguing journeys. Decomposing animal matter, especially the abortive discharges of neighboring cows, the use of ergoted food and smutty corn, may also cause abortion. The best preventive is to avoid all the above causes, not to breed at too early an age, and to allow several periods of heat to pass before the animal is again served. Any animal that once aborts, is liable to a recurrence of the same accident. Keep the stock in the best possible condition, by attention to diet, and to proper ventilation of the building in which they are kept.

HOOVE OR BLOATING IN CATTLE.—Willhide Brothers, Carroll Co., Md., and C. Hoffman, Dauphin Co., Pa., ask us for information in regard to bloating.—This condition is produced by filling the paunch with food to such a de-

gree that the muscular action is interfered with, and digestion prevented. The mass of food consequently ferments, and gives rise to gases which distend the paunch still further, until the organ bursts, the animal suffocates, or relief is afforded. Certain kinds of food, such as clover wet with dew or rain, uncured grain, vetches, heavy growing weeds, etc., when eaten to excess by young animals, are very liable to cause the disease. The animal in its greediness eats to satiety, and the act of rumination is, as it were, forgotten for the time. The preventive treatment is, not to allow access to such food, without exercising great care as to the amount eaten. In the early stages, when the bloating has just commenced, continued exercise, or the dashing of cold water upon the body, may afford relief. At the same time give a pint of soapsuds of moderate strength, or an equal quantity of a solution made as follows: Take half an ounce of chloride of lime, and rub it down in a mortar, with a little water to a creamy fluid, the remaining water being added, the dose may be given at once. If no relief is obtained, a hollow probang should be passed down the gullet into the stomach, which will allow the escape of gas. In urgent cases, the paunch must be punctured, which is easily done by any sharp pointed instrument, and the wound kept open until the fermentation has ceased. The most suitable instrument for this purpose is the trochar, which should be plunged inward and downward, into the distended paunch, in the left side, half way between the hip-bone and the last rib, and at about a hand's breadth below the spinal bones. Withdraw the trochar, and allow the canula to remain in the opening, until the cure is effected. A dose of salts is often necessary to carry off undigested food. The stomach pump, proper probang and a trochar, are necessary articles to be kept in every well-conducted stock establishment.

The Pecan-Nut.

The Pecan-nut (*Carya oliviformis*) is a perfectly hardy tree in south-eastern Virginia, and thrives as well, apparently, as its near relative, the Hickory. We know of several trees, some of them now about fifty or sixty years old; and there are many scattered through the adjoining counties. The nuts from these trees are in all respects—size, flavor, and thinness of shell—the equal of the best Texas pecan. We doubt not the pecan would thrive well anywhere along the coast as far north as Maryland, Delaware, and Southern New Jersey. Here the tree fruits annually, and is generally very prolific. A dozen trees would yield quite a handsome income. Every farmer could have that many trees, growing here and there in odd nooks and out-of-the-way places, though of course it would be better and more convenient to have them all growing together in an orchard. The tree makes good shade, is ornamental, and would make a handsome appearance planted in rows on either side of broad avenues, so often seen in country towns and villages in the old Colonial States.

We recommend the culture of this tree very highly, as being likely to prove profitable from the Potomac and Ohio rivers southward, and in some sections considerably to the north of those rivers. It is not the most valuable of the nut-bearing trees. The European walnut and the almond, both of which will grow and fruit in this section, surpass the pecan in our estimation. Our native white walnut, and especially the chestnut, are superior, to say nothing of the high value of the timber of both these trees. The pecan is well worthy a place in any collection of nut-bearing trees, and certainly every farmer would do well to have his nut-grove, as a source of profit. We are taking steps to establish a nut-orchard of all varieties. B. W. JONES.

Good Words for the Bartlett.

Mr. W. Fulmer, Allegheny Co., Pa., writes us: “In the July *American Agriculturist*, Mr. Theodore Goodrich, after giving his experience with a few varieties of pears, jumps at the conclusion, that the Bartlett is a “universally short-lived” variety. While the Bartlett may be more subject to blight in his section than most varieties, that does not prove it is universally fated. In 1874 we planted a small pear orchard of the following varieties: Bartlett, Clapp's Favorite, Flemish Beauty, Sheldon, Beurre d'Anjou, Beurre Bosc, Seckel, Lawrence, and Duchess. Of the Bartlett, Sheldon, Beurre d'Anjou, Seckel, and Lawrence, we have not lost a tree from blight. Of the other varieties we have lost, from blight, eighty per cent of Clapp's Favorite, ten per cent of Flemish Beauty, eighty per cent of Beurre Bosc, and fifty per cent of Duchess. In extensive pear orchards near here, there are about four hundred Bartlett trees, and of these not more than one per cent have suffered from blight in the last three years. Plant for general crop the varieties that succeed best in your own neighborhood, and in your own kind of soil.

Bone Dust on a Pasture.—C. H. Dent, Fayette Co., Pa.—It makes little or no difference whether bone is applied in fall or in spring; if more convenient to sow it in autumn, it may be done without risk of loss.

Carrying Eggs to Market.—Mr. W. D. Hazer, Lancaster Co., Neb., writes us, that he carries his eggs to market in baskets, which he suspends from hooks on the underside of the high spring seat of the “lumber” wagon. In this way he has no trouble from broken eggs.

A Grass found in Clover.—W. A. Cate, Blount Co., Tenn.—The grass that is new to you is the Meadow Oat Grass, or Tall Meadow Oat Grass (*Arrhenatherum avenaceum*), a most valuable species, whether for meadow or pasture. Especially adapted to the Southern States, and should be better known.

Killing Ants.—H. Hinck, Plaquemines Co., La.—In asking how to kill ants, you fail to say whether they are in the house, or have their nests in the ground. In the latter case, we should try fresh Pyrethrum powder in and around the holes. One correspondent advises to make a hole in the nest and pour in gas tar. Another advocates camphor.

Losses Among Sheep.—The annual losses among sheep in Colorado over one year old from disease, winter and other storms, wild animals, poisonous weeds, snake bites, and old age, are eight per cent. Scab is one of the most troublesome diseases. Wild cats, coyotes, and black eagles are annoying on the prairie lands, while larger animals prey upon the flocks among the foot-hills.

What do you think of Catalpa?

—This question is asked by a number of western subscribers. We know of no other tree that will give such durable wood in so short a time. It would be a mistake to plant the Catalpa to the exclusion of other trees, but it has most valuable qualities, and should be grown wherever the winters are not too severe. The recently recognized *C. speciosa*, is claimed the hardier of the two species.

Killing Live-for-ever.—J. Purdy, Fairfield Co., Conn., writes us: “I have a hand cider mill, I also have Live-for-ever, and a far worse weed, which we call ‘Adder's-tongue.’ Some call it ‘Snap Dragon,’ and others ‘Wench-weed.’ My method is this: After all the juice is out of the pomace, I cover the clumps of the weed with it to the depth of six or seven inches. It will surely kill Live-for-ever.

Paper Making from Wood.—Very few have any idea of the extent to which wood enters into the composition of paper. We have a number of mills for the conversion of wood into pulp, but Norway appears to be the important centre of this manufacture. According to an official report, the exportation of wood paper pulp was in 1875 about eight and a half millions of tons. The quantity exported in 1882 had risen to a little over fifty-nine millions of tons!

What Incubator Shall I Buy!

There are excellent reasons for our not recommending any particular kind of Incubator. The essentials are an equable temperature maintained with little variation; air charged with a sufficient quantity of moisture; ventilation without drafts of changeable temperature; a convenient mode of handling and turning the eggs, and a system of heating whereby the products of combustion are not discharged into the egg-chamber. The beginner should try a one hundred-egg machine, rather than a larger one, and be willing to look after details.

The Steam Plow Outdone.—American farmers have been very slow to adopt the steam plow. Perhaps this was because they were waiting for something better. An inventor claims to have invented a machine to plow by wind power. A sixty-horse-power machine will draw ten plows four miles an hour, and plow four acres an hour, with only one man to manage it. It is rigged with large windmill sails, and besides doing wonders in the field, furnishes stationary power for threshing, grinding, and other operations, and can carry many passengers on the road. The name of this wonderful machine and that of the inventor are not given.

A Grass that Promises to be Valuable.—S. C. Wakefield, Westmoreland Co., Pa. The specimen sent us is the Meadow Fescue (*Festuca elatior*), a species much valued in England as a pasture and meadow grass, but which has received very little attention in this country, though it is found in most of the grass-lands in the older States. The seed of this grass is kept by the leading dealers in farm seeds; about twenty-five pounds are sown to the acre. This species of fescue succeeds best on moist soils, is very nutritious, and yields a remarkably heavy after-math.

Value of Ashes.—Mr. Johnson, Oswego Co., N. Y. Wood ashes is a valuable fertilizer, especially for soils needing potash. Unleached ashes contains seven to ten per cent of potash, and two per cent of phosphoric acid. When thoroughly leached, the potash is reduced to two percent and less. All wood ashes should be saved, and, if not used for ley in soap-making, apply it to the soil before any rains have washed from it the very soluble salts of potash, which are important food elements of all crops. Coal ashes contains but little potash, and its benefits to land are mostly mechanical. It loosens up compact, clayey soils.

The Use of Gas-lime as an Insecticide.—Mr. H. F. Moore, a distinguished agricultural writer in England, in a recent address to the farmers of Frome, upon injurious insects, gave the following upon the use of gas lime in preventing the attacks of insects: "For nearly all crops a good preventive preparation of the land is a dressing of spent gas lime, which should be put on in the autumn and dug or plowed in. If used fresh from the gas works it must be put on when no crop is in, but if allowed to stand and lose its causticity, it is perfectly harmless. It will kill nearly everything, but the earth soon destroys its causticity, and then in the form of gypsum it is a valuable manure."

Postage Rates Reduced.—One cent for each four ounces or fraction thereof, is now the postage rate on newspapers and periodicals of the second class, when sent by mail by other persons than publishers or news agents, postage to be prepaid by stamps affixed. The postal rates on such publications, thus sent, has heretofore been one cent for each two ounces, the reduction being one-half; but it should be observed that this reduction applies only to publications of the second class, which embraces only "newspapers, magazines, and other periodicals issued at stated intervals not exceeding three months, dated and numbered, having a list of legitimate subscribers, and not designed primarily for advertising purposes."

Tomatoes and Tomato Seed.—R. G. Newton, Dakota Terr., writes us that when the "Trophy" first came out, he procured a packet of seeds from headquarters, and by care in selecting the fruit and saving seed, he has the "Trophy" in perfection. The plants are raised in the usual manner; when set out, they are furnished with stakes four feet high, and are trained to a single stem. Each plant gives from three to six clusters of fruit, of three to six tomatoes each. The largest and smoothest fruits are allowed to ripen thoroughly, and before using for the table, the small quantities of seed they contain are scooped out, mixed with water, and allowed to stand a few days; when fermentation takes place, the seeds are washed clean, spread on paper and dried.

Fight the Potato Beetle to the Last.—The fecundity of the potato beetle is enormous. Some insects, that prey upon the farmer's crops, are troublesome for only a few days or weeks, but this pest comes as soon as the potato tops are in sight, and, if unmolested, continues to devour and breed, until the vines have ceased to grow. Last year the beetles had abundant feed up to the close of the season. Farmers have learned to fight them with Paris Green and London Purple through all the early part of their growth, until they think the crop is secure. There is too often utter neglect of the crop in August and September, and the vines are pulled in harvest quite full of beetles and their slugs. Killing them with thumb and finger, or picking and burning, seemed to make little impression upon them. We do not take any stock in the idea advanced by lazy farmers, that this pest is to bave its day, and die out in a few years. Insects, like other creatures, follow the feed, and as long as we cultivate potatoes, we shall have to fight the beetle. The let-alone policy is too expensive to follow. The experience of this season should rub the doctrine into our bones, that the campaign lasts the whole summer. Every slug that is left to mature makes work for next year. If he is hurried in the pile of green vines, he still feeds, matures, burrows, and rises again, and it is not "the resurrection of the just." If you would gain the victory over the legions of Doryphora, there is to be no discharge in your warfare.

Chat with Readers.

Calceolarias do not Flourish.—E. O. Rockland, Norfolk Co., Mass. Calceolarias require no special treatment, other than to be kept as cool as may be, and to be supplied with water in abundance.

Seeding a Wood Lot.—L. A. Jones, Jefferson Co., N. Y.—A wood lot kept free from underbrush and used as a pasture, may have its turf much improved by raking and burning all brush, and sowing a mixture of Orchard and Blue grass seed.

Fall in Tile Drains.—E. A. Miller, Shiawassee Co., Mich.—It is almost impossible to avoid some variation in the grade of tile drains. When a drain changes its grade from three inches to two inches fall to the rod, there will be no danger of sediment collecting, provided there is abundant flow of water.

The Name of a Grass.—G. E. Tilley, Queens Co., N. Y. The grass is *Bromus secalinus*, the well-known Chess or Cheat. You probably will not find the seed at the stores, as it is a troublesome weed. Being a rather showy grass, attempts have been made to introduce it under other names, but without success. While animals will eat it if they can get nothing else, they prefer swale hay.

The Blueberry Fungus.—C. Forkert, Middlesex Co., Mass.—The curiosity which you find growing on the blueberry branch is due to a minute parasitic plant, that attacks the young stem and causes it to assume a very strange shape. The microscopic plant thus preying upon the blueberry belongs to the same group as the mushroom, toadstools, and the various rusts, smuts, and mildews of grains, fruits, etc.

The Blight in Apple Trees.—W. Angus, Douglas Co., Mich., and others. As nothing positive is known about those disastrous visitations to fruit trees, called Blight, no remedy has been found. It will be very severe in a locality, and then completely disappear and not be seen again for years. To cut away the affected part, back to sound wood that is not discolored, whether it takes much or little, is the only advice that can be given.

Trouble with Melon Vines.—J. H. Emmond, Harford Co., Md., writes us, that the leaves of his canteloupe and water-melon vines are drying up, and applications of sulphur do no good. The roots of the vines are probably attacked by the larvæ of the common striped beetle. They are whitish "worms," a third of an inch long. Pull up the wilted plants, and destroy the pest, otherwise the attacked vines will soon die, and the enemy escape to breed destruction the next season.

About Vines.—J. W. Watson, Polk Co., Neb. Virginia Creeper (*Ampelopsis*), Climbing Bittersweet (*Celastrus scandens*) and Virgin's Bower (*Clematis virginiana*), are all so common in the Eastern States, that one who wished them there, would not have to go far before he found an abundance. You can procure the vines at any nursery that keeps a general assortment of climbers. They are all perennials, and after they are once planted, will increase in luxuriance from year to year.

Trouble with Peach Trees.—G. W. Gerrit, Wilmington Co., N. C. From your description there is little doubt that that dreaded disease, the Yellows, has appeared in your orchard. The disease is still under investigation by scientific men, and probably the cause may ultimately be discovered. In the mean time, as trees badly affected will probably not recover, the safer way with these is, to dig up and burn them. Both potash salts and lime have been suggested as remedies.

The Wheat Weevil.—J. L. Munda, Monroe Co., N. Y.—The little pest of your granary is the Wheat Weevil, a beetle one-eighth of an inch long. The eggs are deposited on the grain after it is placed in the bin, and soon hatching, the grub eats its way into the interior of the grains. If the granary is badly infested, it may be best to change the place of storage. Sulphur fumigation is an effective remedy, but must be applied with great care. Thoroughly clean every crack and corner of the granary before another crop of grain is stored in it.

Trouble with Raspberries.—W. Meredith, Erie Co., N. Y., writes us: "The tops of the raspberry shoots which are to bear next year are cut down for six inches or more in a single day, and the next morning appear as if scalded for that distance, the tops being left to wither and decay." ...The trouble is evidently due to some insect, there being several that attack the canes of the raspberry, and the related blackberry. If upon examination a borer or grub of any kind is found, remove the injured tips of the shoots and burn them. This will prevent the increase of the insect.

Catalpa Seed.—W. S. Thomas, Lewis Co., Mo. The seeds are ripe when the leaves fall. The pods should be gathered, and the seeds kept in them until spring, when they are to be sown. Make shallow drills, their distance apart being governed by the manner of working, whether by cultivator or hand-hoe. Distribute the seed thinly, cover lightly, pressing the soil firmly upon them. When the plants are well up, thin to four to six inches apart, and keep them free of weeds. They will usually be large enough to transplant the following spring.

Fire-Proof Compound Elastic Paint.—W. S. Varnum, Plymouth Co., Iowa, states that a party offers to sell the recipe for making a paint with the above name. It is composed of Coal Tar, Rosin, Litharge, and his secret ingredient which renders the paint fire-proof. Trials appar-

ently show the paint incombustible.... We are asked, if it will be safe to make and use this paint. Paints made of Coal Tar, with ground slate and other mineral substances, have been patented, and in buying this recipe there is danger of infringing upon somebody's patent. If the recipe is purchased, it should be with a guarantee against this.

Seeds of Ash and Box Elder.—A. Poitesu, Brown Co., Neb. The seeds of these trees may be sown either in fall or in spring. If sown in autumn, the soil should be covered with straw, to keep the heavy rains from washing them out. If not sown until spring, the seeds should be mixed with dry sand, and kept in a cool place. From half an inch to an inch is deep enough to cover the seeds.... B. S. Moore, Vernon Co., Wis., asks when seeds of Box Elder are ripe, and how long they will keep after gathering. The seeds are ripe in autumn, and should not be kept later than next spring. The seeds on some trees are often all abortive; only those should be gathered that have a plump embryo or "chit" at the large end of the "key."

The Sheep Cough and Sneeze.—J. H. Mack, St. Joseph Co., Ind. The symptoms as described, indicate "grub in the head." The Gad-fly (*Estrus ovis*), lays eggs upon the noses of the sheep. The maggots, when hatched, make their way up the nostrils, to some of the cavities in the head, causing the animals great distress. The grubs live upon the mucus they find, and the next spring leave the head, and become transformed into flies, which will lay more eggs and continue the trouble. Tarring the noses of the sheep, with a mixture of tar and grease, is an effective remedy. The animals are let out by a narrow opening, and each one is touched on the nose with a brush containing the tarry mixture.

Pickling Cucumbers.—N. H. Smith, Howard Co., Neb., and several others, ask us how to "pickle cucumbers by the barrel for market."....The best barrels are whiskey or alcohol barrels holding about forty gallons. Such a barrel requires half a bushel of salt, of the best kind, such as is used for dairy purposes. Remove one head of the barrel, lay in the cucumbers, sprinkling them with salt. They do not need much salt until the barrel is half full, after which it may be added more freely. When the barrel is full, replace the head, having it so filled with pickles that some pressure is required. Having headed it up tightly, turn the barrel on the side, fill it up with water through the bung-hole, and bung up securely. Where pickles are sold by count, keep an account of the number as the barrels are filled.

The "Cotton" of the Cottonwood.—C. H. Carlton, Chicot Co., Ark., sends us specimens of the fruit of the Cottonwood, to show the abundant "cotton" or down attached to the seeds. He asks if this product can be utilized.The Black Poplar of Europe produces a similar down, though not so copiously, which has been used as wadding, and attempts have been made to manufacture it into hats and paper. The expense of collecting it, and the want of strength and elasticity in the fibre, caused the manufactures to be given up. Mr. C. states, that while the supply would be inexhaustible, the gathering of it is a problem. A still more promising material in appearance, the hairs attached to the seeds of the Milkweed (*Asclepias*), has resisted the attempts to utilize it. The fibre being perfectly smooth, it will not spin or felt. Could the Cottonwood down be readily gathered, it might, like the down of the Cat-tails (*Typha*), be used as a non-conductor of heat, to form a material to surround boilers, steam pipes, etc.

Trouble with Squashes.—Mrs. Bibb, Louisa Co., Va., wishes us to tell her how to prevent the vines of the Hubbard Squash from dying, after they get so large as to run. Mrs. B.'s vines are evidently attacked by the Squash-vine Borer, *Ageria cucurbitæ*, a near relative of the Peach Borer. The perfect insect is a moth with transparent hind-wings, while its fore-wings are black. The moth deposits her eggs on the stem of the vine, near the root; the young larvæ, as soon as hatched, make their way into the interior of the vine, where they feed and grow, and at length kill the plant. As to the remedies, it has been suggested that the female insect be trapped by means of sticky fly-paper, placed near the vines, and that they be caught when observed by means of nets. Vines have sometimes been saved by finding the hole by which entrance was effected, and cutting out the intruder before it has had a chance to do much injury. The insect always lays her eggs near the root, and it has been suggested that covering the few lower joints of the vine with soil, will ward off the insect.

Coloring the Hair.—C. J. Rolf, Adams Co., Ill., asks us: "Is there any way to color hair which was originally black-brown, but is now getting sprinkled with white?" He has heard of dyes, and asks us if they are safe in use. He has also heard that a certain comb, which if used frequently will restore the color of the hair, and asks about that....All the hair-dyes of which we have any knowledge, whether offered as a liquid or as a powder, consist chiefly of lead either as an oxide, or in some other form. The powders are to be mixed with water and applied to the hair. The hair contains sulphur, and the union of this with the lead in the dyes, produces a sulphide of lead, which is black. But the application of lead in any form to the skin is dangerous. The comb above referred to is of lead; its constant use will turn the hair black, though with a risk of lead poisoning. But why bother with the hair at all? If spots of gray appear, welcome them. Gray hair upon a woman, who makes no attempt to conceal it, is often a feature of beauty. Why should it not be with men? In using hair dye of any kind, one runs the risk of being poisoned. It is far better to let the hair assume a uniform gray color, than to try to arrest it. Dyed hair deceives no one.

Raising Early Lambs for the Butcher.

JOSEPH HARRIS.

So far as my experience goes, there is no more trouble in raising an early lamb than a late one. In fact, our earliest lambs are almost invariably our best lambs. I would rather have lambs come in January and February than in April and May, and if I could have them earlier, I should prefer it.

Merino ewes will take the ram earlier in the autumn than the English breeds of mutton sheep. For this reason, if for no other, in raising early lambs for the butcher, I should select common Merino ewes, or at any rate ewes having more or less Merino blood in them. There are other reasons why I should select such ewes. There are more of them in the country, and they can be obtained cheap. They are healthy, hardy, thoroughly acclimated, and will stand rougher treatment than the English mutton sheep. They are smaller, eat less, and occupy less room in winter quarters. They will bear crowding better than the large English sheep—or rather, they suffer less, for it is a mistake to keep any sheep in too close quarters. Common Merino ewes, like Jersey cows, when well-fed, give rich milk, and if you want early, fat lambs for the butcher, the mothers, no matter what breed you may select, must have plenty of nutritious food.

I do not say that common Merino ewes are, in themselves, the best for raising early lambs. They are not. I have had grade ewes, the offspring of a mixed Merino ewe, and a Cotswold ram, that would produce larger lambs, give more milk, and the lambs would fatten more rapidly, and mature earlier. But it is not always easy to find such ewes for sale. Those that you find in market are apt to be culls. The butcher, if he has a chance, gets the best lambs. A good plan is to go to some large market and buy a car load of sheep, or three or four times as many as you want. Bring them home, and pick out the best ewes, and then sell the other ewes and wethers to the butchers. Select out more ewes than you expect to want. Some of them may have been already served by a mongrel ram, and some of them will not take the ram as early as you wish. By painting or "ruddling" the ram on the brisket, you can tell each day what ewes are served, and all that are not served up to a certain date, can be disposed of. This will get rid of all that were served before you bought the flock. You can generally sell those which you reject for more than you have paid for them.

I need hardly say that as soon as you bring home the sheep, you should give them the best of pasture, and if they have some extra food, such as cotton-seed cake, linseed cake, oats, corn, or mill-feed, you will get stronger, earlier and better lambs.

Every sheep in the flock, those already on the farm, and those which you buy, should have their feet pared and thoroughly washed with strong carbolic acid. The crude, black acid is the cheapest. I put it on with a common paint brush, being careful not to let much of the acid drop on the body of the sheep. But see that every part of the foot, outside and between the hoofs, is completely wet with the liquid. In a few days go over the flock again. It is little work, and is a safeguard against foot-rot.

Dipping the sheep to kill ticks is also very important, but the scent of the dip is supposed to interfere with the ram, and it is better on this account, when early lambs are desired, to postpone the dipping until all the ewes are served. Merinos are not as liable to ticks as the long-wooled sheep and their grades, but all sheep should be dipped twice in the autumn, say at intervals of three or four weeks apart.

As to the selection of a ram for early lambs for the butcher, opinions differ. There is a notion that the black-faced sheep afford better mutton than the white-faced. There is a certain degree of truth in this, though the color of the head has nothing to do with the quality of the meat. Southdown mutton is not so fat as Cotswold, Lincoln and Leicester mutton—and the Southdowns have dark faces, and the Cotswold, Lincoln and Leicester have white faces. Hence the popular notion.

Cotswold mutton is too fat. Merino mutton is too lean, and there is not enough of it. There is too much tough skin, and bone, and tallow, in proportion to the nice, juicy, tender, lean meat. As a blacksmith once said, a carcass of Cotswold, and a carcass of Merino "should be welded together."

A carcass of a nice, moderately well-fed Southdown, affords better mutton than a large carcass of a fat Cotswold. And it has been supposed, therefore, that to get the choicest of lambs for the butcher, we should use a Southdown ram. This may be true, but it does not necessarily follow. We never get young lambs too fat. The truth of this matter is, that it will probably make very little difference what particular breed of mutton sheep we select the ram from. The real point is to get a good, well-bred ram of any of the mutton breeds.

The use of ram lambs is not desirable, except to a very limited extent, say a dozen or twenty ewes in a season. A vigorous yearling ram, or one two, three, or four years old, can be allowed to run with sixty ewes. If the ram and ewes have some extra food, say a quart of oats each per day, you will be likely to get earlier, stronger and better lambs.

Buckwheat as a Farm Crop.

Buckwheat, though a grain, is not a cereal, and belongs to an order of plants that contains the various smartweeds, bindweeds, knotweeds, docks, sorrel, and the garden rhubarb. The name comes from the German *buch-weizen*—beech-wheat, the shape of the grain being three-cornered, like the beech-ut. The following table shows the chemical composition in one hundred parts of buckwheat flour as compared with that of wheat:

	Ash.	Albuminoids.	Fibre.	Carbohydrates, Starch, etc.	Fat.
Buckwheat	1.22	7.47	0.32	89.46	1.53
Wheat...	0.66	12.53	0.19	85.34	1.28

The albuminoids are less in buckwheat than in wheat; in fact, not much more than half as abundant, while there is a greater amount of starch and fat. Buckwheat is, therefore, shown by analysis to be more fattening and less strengthening than wheat. It makes an excellent feed for pigs and poultry. Many persons believe that buckwheat is not healthful, and causes skin eruptions. Several other members of the buckwheat family produce powerful vegetable principles, and this plant may possess one such, though it is probably not harmful.

New York and Pennsylvania produce sixty-eight per cent of the twelve million bushels of buckwheat now grown in the United States. Only twenty per cent is grown outside of New England and the Middle States. The great fertile prairies and the vast South with its warm climate, are not favorable for the growth of this crop. Buckwheat does well in the hilly regions, where the soil is light and thin. It, in short, flourishes at higher altitudes, with a lower temperature, and under a greater rainfall than other grains.

One great merit of buckwheat is its availability as a second crop, thus replacing another that has been destroyed by frost, drought, insects, or otherwise. It is also valuable as a weed exterminator. The infested land may be tilled until mid-summer and sowed with buckwheat, which by growing rapidly smothers the weeds. Another use is that of a green manure. It grows well on moderately poor land, and makes a large growth of straw, which rots quickly when plowed under, thus adding much vegetable matter to the soil. The uses of buckwheat are various, and the crop, though not a sure one, fills an important place in the economy of many of the best regulated farms.

BUMBLE FOOT IN FOWLS.—A wart-like substance sometimes appears on the ball of the foot, and if allowed to increase in size, it will produce lameness in the bird. This is caused by the fowls being confined upon cement or other equally hard floors. The wart should be removed with a sharp knife, and the cut surface touched with Lunar Caustic (nitrate of silver). Remove fowls thus afflicted to a yard or a coop, with a soft earth floor. The Houdans and Dorkings are most subject to bumble foot.

A New York Farm-house.

Very many of the readers of the *American Agriculturist* are accustomed to think of our Metropolis as a vast block of houses. They will therefore be surprised perhaps to learn that New York City, or what is known as the limits, embrace many farms and gardens, and some of them of extensive proportions. Any one of our readers might start on this August afternoon from Central Park, and drive from morning until night among these farm homes, and still be in New York City. Two or three times a week, one of our editors makes a circuit through this country portion of New York City, in search of facts and incidents for the readers of this paper. On the opposite page is presented an illustration of a fine old homestead, some twelve miles north of the City Park, through whose extensive grounds we drove the other day. They are situated near the Bronx River, and comprise a famous old mansion and many broad acres. The grounds and extensive gardens are maintained by the farmer and gardener, just as they were left by the old gentleman, now deceased, who laid them out very many years ago. On coming to New York to see the sights, it would repay our readers to visit this famous place. You must, however, use considerable tact in gaining admittance to the grounds, as the overseer is very touchy, and wishes you to know that the old gentleman appointed him head man "sixteen year or more ago," and that he is head man still. The engraving at the top of the page, which, like the other, we have reproduced for our readers from drawings made for the Park Commissioners, presents another view not far away, and also within the limits of New York City. All these, and adjoining grounds, are soon to be embraced in new parks. The authorities are appreciating more and more the importance of having purer and better air, if the Metropolis of the New World is to be kept in a healthy condition. These additional parks, which are to be constructed, will not only furnish more pure air, but enable thousands of people to take physical exercise in driving and horseback-riding.

Digging Early Potatoes.

When potatoes are dug during hot weather, some care is needed in storing or pitting them. Farmers who wish to sow winter wheat after potatoes, are obliged to dig them early in September. The work is frequently done in a hurry, and the potatoes are drawn to the cellar, or placed in a pit in the garden or elsewhere. The potatoes are full of juice, are warmed by the sun, and the skin is broken and bruised—conditions, all of them, highly favorable for fermentation and decay. We have rarely met a farmer, who has not at one time or other lost potatoes in this way. "And it served me right," he would say, "because I knew better, but I was in a hurry to get in the wheat, and forgot to take the necessary precautions to prevent their heating." Spread the potatoes out on a barn floor, or if you pit them, put plenty of dry sand with them, and only a few bushels together in a heap. J. H.

Do not Stack Corn Fodder.

In nine cases out of ten, stacked corn fodder will heat and spoil. Sometimes corn fodder sown broadcast is so poor, yellow, and dried-up, that there is not enough sap in it to ferment, and such fodder may be stored on a scaffold or even in a small stack, or mowed away in the barn. But good corn fodder that has been sown in rows, and the land cultivated between the rows, can not be saved in this way. It must be either put into a silo, or tied into bundles and placed in shocks in the field.

A good self-raking reaper will cut the heaviest crop of corn fodder, and throw it into bundles. After they are well wilted, bind up with straw bands or corn stalks, or binding twine, and place the bundles in shocks at convenient distances, and let them remain until October or November. Then make nine of these shocks into one large shock, and tie it with two bands on top. J. H.

A NEW YORK HOME.

Engraved for the American Agriculturist.—(See preceding page.)

Among the Farmers.

New Series.—No. 5.

BY ONE OF THEM.

Perhaps some of my readers think I have too much to say about Jerseys. This breed is, however, in many respects only typical of what may be made of any one of the favorite breeds of cattle. I recently went to Canada, to be present at an "official" test for butter of a little Jersey cow. These tests are very much like horse races. The cow is at her best, the time selected being only a few months after calving. She has either an abundance of grass, or the very best winter feed—roots, meal, bran, etc. She is, so to speak, trained beforehand, so that her appetite, always good, becomes almost insatiable, and then she is supplied with food well adapted to make milk and butter. Every means to induce her to make an abundance of rich milk is fair, except giving her milk or cream to drink, or feeding her abnormal or unusual kinds of food, like oily, or fatty substances. When every thing is ready, or supposed to be, the proprietor requests the President of the Cattle Club to send a committee to inspect the test. The committee men are expected to report for duty at a fixed day. They are entertained at the house of the proprietor, if convenient, and their expenses, etc., are paid by the Club, so that there is no pecuniary transaction whatever between the committee and the proprietor. Milking is usually done at six in the morning, and the same hour at night, but occasionally three times a day—eight hours apart.

The test begins by milking the cow dry, to the satisfaction of the committee. This milk goes as usual to the dairy. The next milking is at the appointed hour, and the weight of the milk is taken, then under the careful watch of the committee, it is set for cream to rise, or to ripen for churning, and the "creamery," or room in which it is set, is locked and sealed by the committee, if possible with their own lock and with their own seal. If the milk is set in a room, the windows as well as the doors are sealed, so that the committee is absolutely certain that the milk cannot possibly be tampered with, either by accident or design, by officious servants, or by some one inimical to the proprietor. The creamer or room must thus be opened, re-locked, and re-sealed for every milking, and when the milk is skimmed. The cream is kept in the same way, locked and sealed, and neither milk, cream, nor butter, until after the final weighing, is ever out of the sight of the committee when it is not thus under the safeguard of lock and seal.

The management of the milk, cream, churning, etc., is left entirely to the dairy people, excepting only the working of the butter, which must be done to the satisfaction of the committee. After the first working and weighing, it is salted with one ounce of salt to the pound, and after proper working, weighed again, which is final. To make the test satisfactory in all respects, the weight of the cow, the date of last calving, and the character of the weather should be noted, together with the temperature at noon, as giving the most correct notion of the day. It is well also to take the internal temperature of the cow, partly as a guide to her feeding and other treatment. A cow thus forced, is usually a little above the normal degree of heat, viz., one hundred degrees, but one hundred and two to one hundred and four degrees clearly indicates a tendency to fever. This under the circumstances is not alarming, though it would be at ordinary times, for when we consider the chemical action involved in the processes of digestion, assimilation, nutrition, and milk secretion, which are disposing of such a mass of strong, and so to speak, "heating" food in a day, one may well wonder that the temperature of the cow does not rise higher. In the matter of feeding, there is room for discussion. If all the cows could be turned into lush pasture with no other food, or if they could have pasture and a certain moderate, but abundant ration of special ingredients, they would stand on a more nearly equal footing. The former would be easy to accomplish theoretically,

and yet there are comparatively few people who could be trusted, without watching, not to give extra grain feed. Human nature is hard to deal with, and while one breeder and his men could be implicitly depended upon, another could not be, and this man of doubtful probity would be the very one to make a hue and cry about the unreliability of the test. It is for this reason that breeders content themselves with the "go-as-you-please race," and look only to the results. The little cow referred to above, besides exercising due diligence in the grass and clover pastures, consumed during the last three days (when the feed was weighed), an average of nearly forty-eight pounds of grain feed a day. This ration consisted of about nine pounds of linseed oil-cake meal, twenty-two of crushed oats, twelve of coarse pea-meal, and five pounds of wheat bran.

Another and entirely different system of testing might be productive of still more valuable results. It is this. Suppose a tight building, or part of a building, to be fitted up to store feed of various kinds and to stable one cow. The cow being accustomed to the place, and at home in it, is there confined for her week's test. Her food—more than enough of each kind, is weighed out and stored in the building with her, except green feed or roots which must be weighed daily. The inspecting committee, having their own lock and seal upon the building, must be present whenever it is opened. The milk and butter test would go on as is now the mode. At the end of the test, the amount of food consumed could be accurately ascertained, and if necessary analyzed, so as to come at its exact nutritive value, and the cow's merit be judged not simply by the amount of butter she has been able to make, but also by the value of her average daily ration. Thus we might find, that one cow would make twenty pounds of butter a week at an average cost of fifty cents a day, while another would yield twenty-five pounds on one hundred cents a day. The comparative economy would be apparent, the twenty pounds of butter would cost but seventeen and one-half cents a pound, while the twenty-five pounds would cost twenty-eight cents each. No doubt greater differences than this would be discovered. It seems that now people really want to find out something "for sure," and they are going about it the right way.

Gates in Wire Fences.

A cheap and simple form of wire gate is shown in the engravings. It consists of the same number of strands as in the adjoining fence, attached to a post in the ordinary way at one end, while the other wire ends are secured to an iron rod. This rod is pointed at the lower end, and when the gate is closed (figure 1), this end passes down through a

Fig. 1.—THE GATE CLOSED.

loop, and the upper end is secured to a hook. In opening the gate (figure 2), the rod is loosened and swings out, when the sharp end is thrust into the

Fig. 2.—THE GATE OPEN.

earth, or a hole in a wooden block set in the ground at the proper place to receive it.

A Barrel Barrow.

Mr. H. W. Clark, Jefferson City, Mo., sends us a description of a barrel barrow he uses in wheeling slops for swine. The barrel with one head removed is fastened in the wheel-barrow frame, as shown in the engraving. It is kept in place by cleats

CONVENIENT SWILL BARROW.

fastened above and below the surrounding parts of the wheelbarrow. This barrow is inexpensive, easily constructed, and while resembling the tub barrow in common use, it holds more, and is more substantial. It can also be advantageously employed in feeding animals and carrying water for plants.

Keeping Cattle in the West.

PROFESSOR S. R. THOMPSON.

The conditions upon which cattle can be kept with the greatest profit in Nebraska are changing. In at least thirty counties in the eastern part of the State, the open range is nearly gone, and in most of this region each farmer must depend upon his own land for pasture. This condition is greatly changing the modes of handling stock.

Those farmers who are forehanded enough to fence in their pasture, and seed at least a part of it to tame grass, will soon find profit in so doing. A boy on a pony is no longer a satisfactory fence. On large tracts, where a little grass more or less is not of consequence, the boy and pony do very well, but when cattle must be confined to a limited area, and to go out of that is to get into your own or your neighbor's corn-field, some other kind of fence is needed. If the large farmers will seed most of their land to grass, keep herds of cattle and buy their grain for feed, they will do better for themselves and indirectly help their poorer neighbors, who have not the capital with which to buy cattle or to fence pastures, by furnishing them a market for their corn and oats near home.

In most country neighborhoods, corn and oats can be bought nearly as cheaply as they can be raised, especially where the labor has all to be hired. There are incidental advantages in this plan. By it a man can keep a larger number of cattle than if he raised all the grain he needs. Having a larger number to sell every year, he can command better prices. He avoids keeping a large number of men and teams to carry on his farm, and the increased burden on his household, caused by the boarding of so many hired men.

It is well known that cattle kept in pasture will thrive much better than when herded. The animals in a herd have less freedom, are driven about more, are not able to get water when they want it, and have to submit to other inconveniences, which do not occur to cattle in a fenced pasture. Experience shows that it is not difficult to convert a prairie grass pasture into tame grass. Keep sowing tame grass seed wherever the prairie grass becomes thin and tramped out, and gradually the one will displace the other. A tame grass sward made in this way is much thicker, and will yield more pasture than one made on land that has been cultivated. The difference is quite as great as it was in the East between pastures made on the original surface of the soil before it was plowed, and that made on land which had been growing crops.

Hops.—Of the forty-six thousand eight hundred acres devoted to hop culture, nearly forty thousand are in New York. Wisconsin stands next with about four and one-half thousand; California has about one thousand acres, and the balance is scattered through fifteen States. The leading hop-growing New York counties are: Otsego, Madison, Oneida and Schoharie. Nearly five-eighths of all our hops are grown in these.

Above-ground Cellar of Brick.

Above-ground cellars are drier, cleaner, and more healthful and convenient than those situated under buildings. We gave in the April *American Agriculturist* a description with engravings of one constructed of wood, and in answer to many inquiries, we now present one made of brick. Stone is equally good, and may be used when cheaper than brick. Figure 1 shows the cellar, exterior; figure 2 is a cross-section, and in figure 3 is seen the ground plan. The two walls are twelve inches apart, the space between being filled with dry saw

Fig. 1.—A BRICK ABOVE-GROUND CELLAR.

dust. Cross-courses tie the walls together, as shown in figure 3. The ceiling is inch-boards joined by tongue and groove, and nailed to the under edge of the tie beams. Two feet of dry sawdust is placed on the ceiling. The roof is sheathed close and shingled, the ventilator being arranged to open and close. The window is double, with a sliding shutter inside. In cold sections, the entry may be

Fig. 2.

Fig. 3.

lined with two-inch lumber. Both doors should be closely fitted. The floor may be grouted, or made of brick laid in mortar. This cellar can be of any desired dimensions; the one shown in the engravings is fourteen by twenty-two feet, and seven feet high inside. It may be covered with climbers.

Preparing the Granaries.

The weevil infested our wheat granaries several years ago, and since then we have been careful to scrub them out once each year with boiling-hot salt-water. If the bins are not all empty when threshing time approaches, prepare those that are empty for the reception of grain, and transfer the old grain to these, and seal the bins just emptied. First, scrub the floor and sides with the boiling briue, being careful that it fills all the crevices. When this has well dried, prepare a thick white-wash, and with it coat the entire interior of the bins, filling the cracks with it. The day before threshing, take an old broom and sweep off the thickest of the white-wash. Since adopting this plan, we have had no pests in the granaries.

If the mice have gnawed holes through the sides, tack pieces of sheet-iron or tin over these, and place well-trained cats in the granary. It is much better to have the boards jointed than to place lath over the cracks, as the inclosed cracks will be inhabited by pests, very difficult to reach and destroy.

The loss occasioned by pests is not measured by what they consume. Mice may not eat much, but

they leave crumbs plentifully behind them, which detract from the appearance of the wheat and lower its price, when it is sent to market. Weevils may not destroy much grain, but many millers will not buy grain infested with them at any price.

Hookertown Views of the Dog Question.

TIMOTHY BUNKER, ESQ.

The Farmer's Club and the agricultural journals make Hookertown very lively. The last topic stirring this rural region is the dog question. And nothing comes nearer the heart of the average landholder than his dog. The proverb, "Love me, love my dog," must have originated in the rural districts. The dog owner here prizes his cur of low degree more highly than the aristocrat his St. Bernard or his fox hounds. Old Bose is the very jewel of his establishment, and any insinuation that he chases sheep, kills turkeys, steals bones from neighbor's back-doors, or snaps at school children, is resented as a personal insult. Bose is a well-bred dog, grew up in the family, and never did any body any harm. Malice must be at the bottom of all evil reports about him. If one inquires of its owner what is the brute good for? the responses are various and characteristic.

George Washington Tucker says: "that yaller dorg of mine is worth his weight in gold jest to watch the house at night. I'd jest like to see any tramp enter my yard when old Tige is 'round; he'd make mince meat on him quicker 'en you could say Jack Robinson." The necessity of a watch dog about will be understood when it is known that Mr. Tucker lives in a hired shanty, rent two dollars a month; live stock—one shot, five hens and a rooster; household goods worth about fifty dollars! Burglars are so prone to visit such establishments that old Tige must stand sentinel inside by night, and worry his neighbors by day, the year round. Jake Frink is among the most stalwart vindicator's of dog rights. "I kalkerlate that I've jest as good a right to keep a dorg as the next man, legislator or no legislator. What upon 'arth du they 'spect a feller is gwine to du with skunks and woodebucks and other varmints, ef they tax the dorgs out of existence. With woodebucks on y'er beans and clover, skunks after y'er eggs and chickens, and uosein' round y'er garden-sass, and coons in y'er eoru, their'd be a mighty lean look for Thanksgiving, I tell ye. The Guverner might jest as well uot issuo his proklermashun. I'm agin this dorg law."—A look at Jake's garden or eoru-field in summer, will impress any one with the high value of dog power as an aid to cultivation.

Seth Twiggs thinks dogs worth having for company. "Ye see I'm lonesome sometimes, even with the old pipe and Tirzah for company. Mr. Spooner preaches that it's scripture doctrin, 'It's not good for man to be alone.' Jess so, I believe that, I don't know what the Almighty made dorgs for, if it wern't fur company. Children take naterally to dorgs, as ducks du to water. I guess they are made to go together. The fellers we sent up to Hartford had better take care how they unsodder what the Almighty has put together. This tinkerin' at the State House is bad business. I'd really like to see statesmanship once in a while." The smoke was very thick about Seth's head.—Benjamin Franklin Jones says, "I believe in protectin' sheep but can't see jest how this dorg law is gwine to du it. It 'don't seem to thin off the dorgs much. They multiply jest about as fast. What we want is an improved breed of dorgs. Shepherd dorgs won't harm a sheep, and are a necessity for sheep-keepers. We can breed the thirst for blood out of the common cur, civilize him, and make him indispensable on the farm. He is in the process of evolution, working up toward the shepherd type. It seems a great waste of these hundred or more generations of training, if our law-makers are to arrest him in mid career, as an unfinished, abortive sample of the Creator's works I take some stock in evolution." Jones is one of the philosophers of our town. He lives in a tenement house—never owned a sheep, and probably never expects to, but

he has heard of Darwin, and, like others who have not read him, thinks he understands evolution.

These, and many other things equally learned and lucid, are said in behalf of the cur which is overwhelmingly the favorite type of dog in the rural districts. I admit for argument sake that even the cur has his legitimate uses on the farm, and it is not quite the fair thing to exterminate him because he is the greatest hinderance to sheep raising. The most devoted dog fancier and breeder of pups, must admit that he is a dangerous animal to have around, and that the owner of a dog, of whatever degree, ought to guard the public against the evils of his running at large, and be held to strict responsibility for the damages to his neighbor. In many ways the dog is a heavy tax on his owner, and a terrible nuisance in the community. Every farmer having room for sheep, and wishing to raise them, wants legislation against dogs before embarking in this business. Statistics show in part the thousands and tens of thousands of sheep killed by dogs in every wool-growing State, but cannot show the loss to this industry, because of the multitude of farmers who fear to raise sheep on account of this annual slaughter. It is one of the most profitable and helpful branches of agriculture in all the older States. Supplying lambs and sheep to butchers pays abundantly, and wool is a good crop to raise at long distances from market. There is nothing like sheep to keep down brush and briars, and to improve the quantity and quality of the grasses. Many farms now growing to brush in all the Eastern States, might be made profitable if only the dogs were out of the way.

Foot Rot in Sheep.—French Treatment.

Foot Rot in sheep, as is well known, is an inflammation of the whole hoof, accompanied by the formation of blisters which break and become ulcers,

Fig. 1.—A LIME-WATER TANK.

discharging fetid matter. It usually appears in the fore-feet first, and when sheep are seen to favor these, often to the extent of grazing upon their knees, they should be looked to at once. In France the milk of lime has been found useful in preventing the spread of the disease, and for the cure of

Fig. 2.—A SHEEP HOLDER.

mild cases. Shallow tanks or trays are placed at the doors of the sheep barn, and the animals, as they go out or in, bathe their feet in the liquid. These tanks are about ten feet long, and of a width suited to the doors of the sheep-barn, as

shown in figure 1. The sides are about four inches high, and there are strips nailed cross-wise on the bottom to prevent the animals from slipping as they pass through the liquid. Lumps of quick-lime are placed in these tanks, which, on the addition of water, slake, fall to pieces, and mixing with water form the milk of lime, which is another name for whitewash. If the sheep on coming out bring litter with them, this should be removed from the tanks by means of a rake. Where the disease has established itself, the sheep must be treated individually. The diseased horn of the hoof must be cut away with a sharp knife, and all ulcers cleansed. A concentrated solution of sul-

Fig. 3.—THE HOLDER IN OPERATION.

phate of copper (Blue Vitriol or Blue Stone), or a caustic ointment of some kind should be applied. A favorite ointment for this disease consists of:

Finely Powdered Blue Vitriol..... One pound.
 Finely Powdered Verdigris..... Half-a-pound.
 Linseed Oil..... One pint.
 Pine Tar..... One quart.

The feet are thoroughly smeared with this, which is not washed off, as a solution would be, by the wet grass. For the ready treatment of the feet the French shepherds make use of the apparatus shown in figures 2 and 3. This consists of four hobbles, *a, a, a, a*, figure 2, fastened to an elbowed piece, *b*. The device is attached to the waist of the operator by means of a girdle, *c*. The strap, *d*, is used to secure the legs of the sheep, which, when operated upon, are held as is shown in figure 3.

A Prize Piggery.

CHAS. H. COBURN, N. H.

The size of the piggery, shown in figures 1 and 2, is twenty by forty-five feet. The yard-doors, *a, a, a*, figure 2, are two and a half by three feet, and raised by cords from the passage-way. The doors, *b, b*, are for the passage of the visiting hogs. There is a sliding-door placed at the end of the piggery against which a wagon may be backed for loading

Fig. 1.—EXTERIOR OF PIGGERY.

and unloading. The passage-way doors, *c, c*, are hung with strap hinges, fastened with hooks and staples. There are five windows on the south side, made with sliding sashes. On the north end of the building, over the pens, is a floor of matched boards, eight feet wide and thirty-two feet long,

and six feet above the main floor. This furnishes abundant store-room for corn, etc. The floor in the kettle-room is laid with seven-eighth-inch hemlock boards. The floors of the pens are of two-inch matched planks, with the cracks well filled with coal-tar, and raised two inches above the passage. There is a cellar under the kettle-room for storing roots. It has a twelve-inch wall laid in cement, and a double bulkhead door, through which the roots are taken. The balance of the building rests on stout chestnut posts, and is planked upon the outside to the sills. The outside of the piggery is clap-boarded with spruce, and the roof is covered with pine shingles. Two ventilators made of tin, run through the ridge of the building. The chimney starts from the bottom of the cellar and reaches three feet above the roof. The partitions on both sides of the passage-way, and between the pens, are made of two-inch plank, three and a half to four feet high. There is a trap-door over the cellar doors, and above this, a pole with hooks, upon which to hang dressed hogs. The following is the estimate of materials and labor required:

2 sills, 6x6, 45 feet long.	26 pieces studding, 2x4, 6½ ft. long.	\$ 42 00
3 " " " 33½ " "	15 end studding, 2x4, 15 ft. long.	3 60

Patented Inventions for the Grain Field.

The whole number of patents issued for plows up to the year 1880, was five thousand five hundred and eighty-five. Of these, there are fifty-six steam plows, and eight hundred and eighteen wheel plows. The patents for harrows and diggers number one thousand seven hundred and forty-six. The two thousand three hundred and fourteen patents for seeders and planters include five hundred and forty-three broadcast sowers, and one thousand and twenty-nine corn planters. The total number of patents issued for harvesters, is six thousand two hundred and thirty-five, among which are three hundred and ninety-eight self-binders, nine hundred and fifty-four self-rakers, and two hundred and fifty-two corn harvesters. Two thousand three hundred and seven patents for threshers have been granted, including two hun-

lessening hand-labor. The effect of the combined results of inventive genius, *i.e.* Yankee ingenuity upon us, as a people, is not easily comprehended.

The Zebra Rush.

Among the Japanese plants which are attracting the special attention of American and English growers in the present furore for everything Japan-

THE ZEBRA RUSH.

ese, is the Zebra Rush. The leaves are transversely banded with white and green, as seen in the engraving, and bear a striking resemblance to porcupines' quills. The cylindrical leaves of a strong plant are two feet or more in height. The plant has passed into the collections of florists, and proves to be a form of *Scirpus Tabernaemontanus*, a well known European and Asiatic species. In justice to one who has done so much to enrich our gardens with rare Japanese plants, we should say that this Zebra Rush was sent home by Thomas Hogg long before the Japanese presented it at the Centennial Exhibition, but his plants died. Variegated leaves with the white markings disposed lengthwise or in blotches, were quite common, but plants with the markings disposed transversely, were not known before the introduction of this rush. Several years after, a variety of *Eulalia (Miscanthus) Japonica*, with transverse markings upon its leaves was introduced from Japan, that country of interesting plants. Those who consider

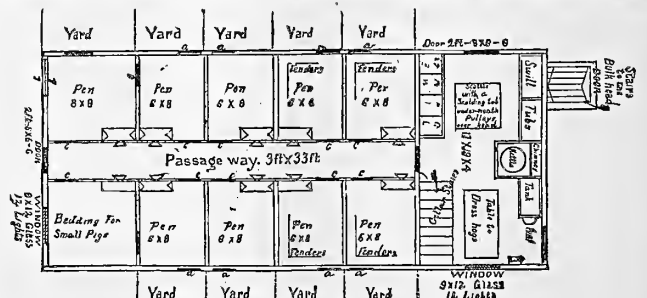

Fig. 2.—GROUND PLAN OF PIGGERY.

dred and six corn husking machines, and three hundred and sixty-nine corn shellers.

Over ten thousand patents have been issued for implements and their improvements, connected directly with the grain crop. The farming classes are intelligent, and are quick to devise means for

all white markings upon plants as due to disease, will be puzzled at this rush, which presents such an alternation of green and white. Very probably the Zebra Rush is hardy; having but one plant, we have not cared to test the matter by leaving it exposed in the open ground during the winter.

Plant the Bulbs Early.

The lover of flowers can receive no more ample return for the money expended, than for that which he lays out in Holland bulbs. In autumn he buys and plants a lot of "onions," as the French call them, and in early spring is rewarded by a magnificent display of flowers. The principal bulbs included under the name of "Holland" or "Dutch Bulbs," are Hyacinths, Tulips, Narcissuses of many kinds, and Crocuses. There are others, but these are the leading kinds. We are glad to observe that a new interest is awakened in these charming flowers, especially in the species, and the many varieties of the Narcissus. In the spring of the present year, flower fashion set strongly in favor of the Narcissus; a neighbor of the writer, having planted largely of Narcissus bulbs left over from last fall's sale, cut the flowers and sent them to market. His returns for the flowers were greater than he could have received had he sold the bulbs, while these, having a year's growth, will give a fuller crop of flowers next spring. To have the best success with Holland bulbs, they should be planted early. The time for planting in this country, must of course depend upon the date at which they are imported and offered for sale by the dealers. As soon as the bulbs can be procured, they should go into the ground. A safe rule is to plant the bulbs their own depth below the surface, and to set them twice their width apart. Planted early, the bulbs have ample time to form abundant roots, which will later be of service in promoting a vigorous growth of foliage and bloom. Bulbs are admirable window plants, and are easily managed. Keep the pots at a low temperature and in the dark, to cause roots to form before the leaves begin to develop, a condition necessary to success. All who propose to plant Holland bulbs, whether in the open ground or in pots, etc., for house-blooming, should procure them as early as they are offered for sale by the dealers, and plant at once.

Crocuses in Grass.

Adjoining the railroad station at which the writer takes cars for the city, is a triangular piece of ground, that a neighboring florist keeps bright with flowers the whole season. There is a long border for flowers, and on both sides of this is a broad strip of grass, which is kept mown as a small lawn. A year ago, the florist referred to planted crocus bulbs in clumps all over the grass. An opening was made in the turf, from three to a dozen crocus bulbs were planted in each opening, and the sod replaced. The past spring this grass plat was gay with the bright flowers of the crocuses, which kept in bloom for several weeks. So attractive was this station garden, that in several cases passengers stopped over until the next train, in order to more carefully view, and make inquiry about, the flowers. Planting in clumps in the lawn, is the best method with all save the large, named varieties of crocus, which may be planted in clumps in the border. Crocuses are among the earliest flowers to appear in spring. They bloom and their flowers fade away, before the grass needs mowing. Bulbs, thus set

out, will increase in strength and numbers and last several years. This method of planting may be commended to all who have lawns large or small.

A New and Fine Narcissus.

The bulb season in England this year is marked by the sudden appearance of a flower that, on account of its large size and great beauty, makes a

A NEW NARCISSUS, "SIR WATKIN."

sensation. An engraving in the "Gardener's Chronicle" (London), allows us to give the life-size portrait of this new comer, which has a history. The flower was exhibited at a meeting of the Royal Horticultural Society, by Messrs. James Dickson and Sons, of England, as "James Dickson," and as such was awarded a certificate. Now comes Mr. William Pickstone, who claims that the variety originated in his garden in Wales, some sixteen years ago, and that he has grown and multiplied it there and elsewhere as "Sir Watkin." Leaving the Society to settle the question as to the priority of name, we may say that the variety is probably a chance cross between *Narcissus biflorus*, and some other, and exceeds in size the Emperor, Horsfieldi, and others heretofore regarded as the finest varieties. The segments of the flower, with a spread of over four inches, are of a pale canary yellow, and the cup, which is handsomely fringed, is of a rich gamboge-yellow. Unlike some other large varieties, this is exceedingly fragrant. That so striking a flower should have been cultivated for sixteen years before coming to public notice, is accounted for by the fact that its discoverer is a farmer who grew and increased the bulbs for his own gratification. Some of the bulbs having passed into the hands of the firm above mentioned, they at once brought such a remarkable novelty to the attention of horticulturists.

Night-blooming Cereus as a House-plant.

THOMAS SHEEHAN.

There are a number of night-flowering Cereuses, but the one especially known as the Night-blooming Cereus is *Cereus grandiflorus*, which, when in full bloom, presents a rare sight. Some of the flowers of the night-blooming kinds are exceedingly fragrant, notably *Cereus triangularis*, a single flower of which, when well open, will fill the air of a room with its pleasant odor. These plants can be made to bloom freely, by keeping the soil quite dry, and allowing them very little pot-room, as they depend more upon the atmosphere than the soil for their growth. We have known large plants of *Cereus grandiflorus*, to produce as many as twenty fine blossoms each in the course of a season. We have found that liquid manure, if applied to these plants about once a month, and when the soil about them is very dry, will work wonders with them, and when a rapid growth can be obtained, there will be no trouble in having an abundance of flowers at regular intervals. Care must be taken not to have the liquid too strong. A small quantity of brick dust, mixed with the soil in which they are growing will be beneficial. These species of Cereus are easily propagated by cuttings, which will root readily in sand of any kind. Being of a slender habit of growth, and rather rampant, they should have some sort of support, and it is advisable to either train them to a trellis, or upon wires or a string stretched over and along the window sash. We have had a number of flowers of a pure feathery white, *C. grandiflorus*, that were over fifteen inches in diameter; this is the best of the night-flowering species. Formerly not only the different species of Cereus and of other genera of the Cacti were much more frequent as house plants than at present. They require very little care, and in their magnificent flowers give an abundant return for the little

attention they need. There are some kinds that bloom in winter, but the great majority are summer flowering, and take a long rest in winter. They will endure a great amount of neglect, but must be kept where they will not be frozen.

Fall Planting—Stripping the Leaves.

No questions at this season are more frequent than these: Do we advise fall planting?—Is it proper to strip the leaves from nursery trees?—As to fall planting, the answer would differ with the locality. Where the soil is in good condition, and in localities where there is a usually long autumn, and the winter does not shut down suddenly, there is much to be said in favor of fall planting of orchard trees of all kinds. Should fall planting be undertaken, and the weather become unfavorable, the trees, being at hand, can be heeled-in and ready for planting next spring. As to stripping the leaves from nursery trees, especially from peach trees, we regard the practice as a legitimate one. If the leaves have done their work, and can be removed by merely running the hands along the branches, no harm can come from removing them. Leaves that can be readily removed, can be of no further use to the tree. Hence we say, if the leaves can be stripped with great ease, no harm can come of stripping them.

The Artillery Plant.

Among the most interesting green-house plants, is *Pilea serpyllifolia*, popularly known as the Artillery Plant. It is a succulent plant with numerous branches and very small leaves. It has, as shown in the engraving, such a fern-like habit, that we have known it to be cultivated in the belief that it was a fern. The plant is a native of Central America, and needs a warm green-house. It will do fairly well kept in a warm, sunny window, but if it gets chilled, it loses its leaves and presents a most sorry appearance. Its flower buds, which are very numerous and pinkish, are smaller than the head of a pin. If when the sun is shining upon it, the plant be gently sprinkled with water, each little

THE ARTILLERY PLANT (*Pilea serpyllifolia*).

bud pops open, and the stamens emit their pollen. When many flowers thus open at once, there is produced a smoke-like cloud of pollen, which is quite striking, and makes the name "Artillery Plant" appropriate. The plant belongs to the Nettle Family, and may be readily increased by cuttings. On account of its fern-like appearance, the plant is sometimes used with other succulent plants in working out ornamental designs in bedding.

"Do Potatoes Mix in the Hill?"

The above question, variously expressed, comes to us every now and then. This time it is from "A. W. M.," Alamosa, Col., who writes: "Please state whether potatoes of different sorts, planted together, will affect one another so as to produce tubers different from the seed planted, *i. e.*, the potatoes, when dug, will be different from those planted in the ground?"—We might answer this with an unqualified "No," as the potatoes do not "affect one another." Such an answer would not be satisfactory, in view of the fact that occasionally potatoes, when dug, are found to be "different from those planted in the ground." Some farmers are so well assured that potatoes will "mix in the hill," that to avoid it, they take great care to plant their different varieties as far apart as possible. It is often very inconvenient to plant the varieties at a great distance apart, and farmers should understand that all the care taken to do this is utterly useless. They should be assured that the tubers of one variety can have no influence upon the tubers of another kind, however near together they may be planted—even if in the same hill. It may be asked: "If they do not mix, how do you account for the fact that potatoes are sometimes dug which are unlike those planted as seed?" Similar changes occur in other plants in which there is no suspicion of "mixing." It is a well established fact that a branch of a peach-tree has more than once borne

nectarines, and a nectarine tree has borne peaches. A Black Hamburg grape vine, having been injured by fire, threw up a new shoot, the grapes upon which, to the surprise of the owner, were white instead of black. Florists are aware that many of their choice greenhouse plants, notably the bouvardias and geraniums, have given flowers on new branches, which were quite unlike those upon the rest of the plant. A few years ago a noted florist obtained two very distinct roses from a well known kind. Two branches produced flowers quite unlike each other, and so different from the original sort that they were propagated and are now in commerce as new varieties. Cultivators call these departures from the original plants "sports;" botanists call them "bud variations." This last is a more precise term, as each branch proceeds from a bud, and whatever causes these variations must have its effect upon the bud. The application of this to the variation in the potato, will be apparent when we consider the real nature of the potato, which is a tuber and not a root, and has no more connection with the root than if it grew upon the stem, above the surface of the soil instead of below it. If a potato plant, or vine be dug up just as the new potatoes begin to "set," the real nature of the tuber may be seen. Underground stems are produced, which begin to swell at the ends, and these ends increase until the full size of the variety is attained. These tubers, unlike the roots, have buds, or "eyes," as they are popularly called, corresponding to the buds of an above-ground branch. When a seed potato is planted, one or more of its eyes start, the growth from one eye, or bud, corresponds to, and really is a branch; this bud may vary, though we do not know what causes it to do so any more

than we know the cause of the variation in the bud of the peach or the rose. All that proceeds from that bud or eye, whether above-ground or below, will be unlike the seed potatoes that were planted. We do not notice differences in the above-ground growth of the vines, as they are not the portion for which the plant is valued, but differences in the tuber at once attract attention. These differences are shown in size, shape, color, time of ripening, etc., that of color being the most striking. The "Late Rose" was a sport (bud variation) from the "Early Rose;" here the important difference was in the time of maturing. In this case, the variation was noticed in the plant, or vine, one hill of Early Rose remaining green and still growing, long after all the other plants were completely dead.

Easily-Made Fruit and Flower Baskets.

While our Yankee ingenuity is shown in many directions, we are quite behind other people in basket making. One who visits the markets in Canada, discovers that berries are offered in curiously

Fig. 1.—RECTANGULAR BASKET.

shaped receptacles, made of the bark of the Canoe Birch. If he finds in the New York City market, flower baskets, neatly wrought of green rushes, he may be sure that the maker is a woman living in Weehawken, or some other of the many settlements of Germans in New Jersey. Baskets to hold fruit and flowers may be readily wrought out of very simple materials. Straight sticks of any kind of brush, with the bark on, make pretty rustic baskets.

Still neater ones are made from the Southern cane. These canes are sent North in great numbers for use as fishing poles. The long upper ends of these canes, not being strong enough for anglers' use,

Fig. 2.—SIX-SIDED BASKET.

are cut off, and sent to market separately for the use of florists, who find them very convenient as supports for plants. The small canes, by the aid of fine copper wire, may be made into the forms shown in figures 1, 2 and 3. Straight sticks of any kind may be wired together in the same manner. If used for flowers, these baskets may have a lining

Fig. 3.—HANDLED FLOWER BASKET.

of stiff brown paper or paste-board, to hold the moss in which the flowers are set. Figure 4 shows a basket very popular in England. It is largely made of splits in one of the English rural districts. These baskets were shown at the first World's

Fig. 4.—THE QUEEN'S BASKET.

Fair. Her Majesty saw them, and ordered one for each of the Royal children. This at once made the basket popular, and the makers at once adopted the name of "The Queen's Basket."

New Destroyers of the Cabbage Worm.

We say "the Cabbage Worm," being well aware that there are three, if not more caterpillars of as many species of butterflies that are popularly known as "Cabbage Worms." These are so nearly alike in both appearance and habits that, for all practical purposes—that is, their destruction, they may be treated as one. It is a most wise provision in Nature, that when an insect attacks our crops in destructive numbers, its insect enemies increase in proportion. Indeed, were it not for this help, our own labors in destroying injurious insects would avail but little. In England, to which we are indebted for some, at least, of our cabbage worms, great help is received from two Ichneumon flies, which by their parasitic habits, cause the death of the worms, by depositing their eggs upon the caterpillars, or upon the chrysalids. One of these, the *Microgaster glomeratus*, lays its eggs, sometimes more than sixty, in one caterpillar. These hatch, and the maggots from them feed upon the interior of the caterpillar, not destroying its vitals. At the time for the caterpillar to turn to a chrysalis, it dies, and the young maggots come out and spin their little cocoons on the cabbage. These co-

eons look like eggs, but should not be destroyed. Another fly attacks the chrysalis when just formed. This (*Pteromalus brassice*), lays some two hundred and fifty eggs upon the tender skin of the chrysalis, the young maggots eat their way into the interior, and live upon its contents, of course destroying the foster insect. The engraving shows the cabbage butterfly at 1, its eggs at 2, caterpillar at 3, chrysalis at 4, and the Ichneumon fly of the natural size at 5, and magnified at 6. One parasitic fly has been found attacking the cabbage worms in this country; whether it is of this species, we are unable to say. Wherever such flies, or their little cocoons are discovered, they should not be destroyed.

NEW DESTROYER OF THE CABBAGE WORM.

lis at 4, and the Ichneumon fly of the natural size at 5, and magnified at 6. One parasitic fly has been found attacking the cabbage worms in this country; whether it is of this species, we are unable to say. Wherever such flies, or their little cocoons are discovered, they should not be destroyed.

What Cuts Rose Leaves?

Mrs. S. Walker, Bergen County, N. J., writes us: "I find the leaves of our rose bushes are badly disfigured. Pieces forming a part of a circle are, as in the specimens sent, as neatly cut as if the work was done with a pair of very small scissors. What cuts the rose leaves?"—The leaves show that one of the Leaf-cutter Bees has been at work upon them. These bees belong to the genus *Megachile*, of which there are several species. They are all provided with stout jaws, which are able to cut the leaves like scissors. The engraving shows (reduced) the manner in which the rose leaves are cut. The pieces of leaf are used to build a nest, which may be in a crevice in a tree, or under a board. One of the nests is shown in the lower part of the engraving. Having built her cell, the bee places in it a supply of pollen for the food of the larva, and finally deposits an egg in the cell, which is then closed up, and another is begun.

LEAF-CUTTER BEES.

One writer states that he turned over a board, under which he had noticed a bee at work, and found that she had made thirty cells, all of pieces of rose-leaves. Upon making an estimate, he found that about a thousand pieces of leaves had been used. It is not likely that these bees, also called Upbols-terer Bees, will ever be a serious pest to rose-growers. They may be kept in subjection by watching them as they leave the rose bushes, ascertaining where they build their nests, and destroying these before the new brood of bees appear.

Broadcasting and Drilling-in Wheat.

There are two methods of sowing wheat—broadcast and in drills. By the first the seed is scattered irregularly upon the surface of the prepared soil, and covered with a harrow or cultivator. Broadcast sowing may be by hand, when the expense of a machine is saved, or by a broadcast sower, with which the work is rapidly done. Cheapness and rapidity are the principal advantages of broadcast sowing, either by hand or with a machine. More or less of the seed remains upon the surface of the soil after the harrow or cultivator has passed, while the covered grains are at various depths—some too deep and others too shallow for their best development. There is therefore some loss of seed, which must be allowed for in the seeding. Sowing in drills cannot be done by hand, and the cost of the machine must therefore be counted when this method is considered. The advantages of drilling, however, far outnumber those of broadcasting, so that drills are now very generally used in the wheat-growing regions. With a drill properly adjusted, nearly every grain can be placed at the depth best for germination and growth, and well separated from all other neighboring grains. There is much less seed required in drilling than in broadcasting, making an important saving in favor of the former method. An average of two bushels per acre is used broadcast, while one-half to five-eighths of this is sufficient with the drill.

Wheat that is drilled-in "winter kills" less than where it has been scattered broadcast. This winter killing is caused by the frequent freezing and thawing of the earth near the surface, which raises the roots out of the soil, and exposes them to the drying air and sun. When sown with a drill, the grain is in a slight furrow, and the freezing and thawing does not so easily lift the plant; it also tends to fill up the furrows made by the teeth of the drill, and thus adds protection to the roots which may have become exposed. Under the best conditions wheat should be sown about one inch deep.

Valuable, but Little Known Grasses.

Timothy is so generally grown by our farmers, that one might suppose it to be the only grass suited to our climate. One reason for its culture, to the exclusion of other grasses, is the reputation that Timothy enjoys among buyers of hay. A city livery stable keeper, or other purchaser, will not usually accept any other hay than Timothy. As a hay crop, this grass has much to commend it, but there are others quite as valuable, while as a pasture grass, it is one of the poorest. It is very difficult to break up a long established practice, yet we are glad to know that our frequent advocacy of Orchard grass in past years, has induced many farmers to sow it instead of Timothy, and they have found the change profitable, especially if the field was ultimately to be pastured. Among other grasses to which farmers should turn their attention, is the Tall Meadow Fescue (*Festuca elatior*). This grass presents itself in three forms. The typical Tall Meadow Fescue (*F. elatior*), is three or four feet high, with an ample spreading panicle and broad leaves, as in the engraving. The Common Meadow Fescue (*F. pratensis*), is not so tall as the foregoing, and with a close, slightly branched panicle. The Spiked Meadow Fescue (*F. loliacea*), has the flowers in a spike, i. e., the cluster is not branched. These three forms were regarded as distinct species, indicated by the names above given. They however run into one another, and while botanists regard them as forms of one species, the seeds of the varieties are kept distinct by seedsmen. Though rarely sown in this country, these forms have been introduced, and one or all of them may be found in established grass lands, especially in the older States. In nutritive quality, the three forms are regarded as about equal, the principal difference among them being in size.

The second form (*F. pratensis*), is known in Virginia as "Randall Grass," and in North Carolina as "Evergreen Grass," and in the mountainous por-

tions of both States is highly esteemed as a pasture grass, especially for sheep. These Fescues are very valuable on account of their adaptability to moist and even wet or marshy lands, and as their roots penetrate the soil to a great depth, they endure the drouths remarkably well. The seed catalogues advise sowing forty pounds of

TALL MEADOW FESCUE.

seed to the acre; a good stand has been made with half that quantity of seed of the best quality. Another, and related species, deserving attention, is the Sheep's Fescue (*F. ovina*). This was described and illustrated in February of last year. Like the species already noticed, this has several well marked forms, and is as valuable for elevated and dry soils, as is the other for wet ones. It is affected by the character of the soil to a remarkable degree.

Sow Now for Spring Flowers.

While our gardens present a much greater variety than did those of a half century ago, there are some plants in which the old-time gardeners excelled. We do not see such beds of Pansies, or of Rocket Larkspurs, as were then the pride of the gardeners. Success with Pansies is mainly due to sowing the seed in autumn. If the seed is sown in spring, by the time the plants begin to bloom hot weather comes, and the flowers become fewer and smaller. In order to have the flowers in spring, sow the seeds early this month. Make a spot of rich soil fine, and level the surface by pressing it with a board. Sow the seeds, sift a little soil over them, and press down firmly with the board. When the plants are an inch high, transplant them to the place where they are to flower. The plants are quite hardy, and all the winter protection they need is a little brush to keep the snow from pressing too heavily upon them. The Rocket Larkspurs are, unlike the tall ones, annuals. A bed of them is as showy as one of Hyacinths. Sow in a well enriched bed this autumn, but leave them to flower where they were sown. The bed may be covered with brush during the winter, and if the plants are too much crowded in any part of the bed next spring, thin them by cutting out the surplus. They do not transplant satisfactorily.

Plush and Satin Picture Frame.

The pretty picture frame shown in the engraving, is easily made. Cut two pieces of paste-board the size desired for the frame, one for the back and the other for the front. In the latter make an oval opening large enough for the picture, and cover the paste-board with garnet plush, drawn smoothly over the surface. Cut the diamond in the plush somewhat smaller than that in the paste-board; and "slash" the edges around and glue

A PICTURE FRAME OF PLUSH AND SATIN.

them on the back. Fasten the mat, glass, picture, and back piece all together with a binding of stout muslin glued on. Place satin ribbon around the frame, as shown in the engraving, and finish with a neat bow in the left hand corner.

A Ball Holder.

The pretty little ball holder, shown in the engraving, will be appreciated by any one who does much knitting. It is intended to hang on the arm or back of the chair, and to hold the ball of yarn so that it can unwind easily. A piece of paste-board, six inches wide and eighteen inches long, with a small hole in the middle, is made into a tube by sewing the edges together. It is covered with

A HOLDER FOR KNITTING YARN.

a piece of bright silk or cashmere, by catching the edges across on the wrong side. The cover is cut over the hole, and the edges drawn in on the wrong side. Insert a lining of silk or muslin to cover the long stitches. A piece of material four inches deep is sewed around each edge, and drawn up by a narrow ribbon run in a casing. A ribbon is also tacked across from side to side, and each end finished with a small bow. The ball is placed in the

holder through one end, and the end of the yarn or silk is taken out through the hole in one side.

Use for Old Wash-Stands.

The old pine wash-stand, now tacked away in the garret, but so common a few years ago, the one with a hole in the top for a wash-bowl, bars for towels, and a drawer and shelf below, is a treasure not to be despised. Do you want a pretty Queen Anne table, for books or music, remove the back piece and bars, and nail a smooth board over the top to cover the hole. An ounce of shellac dissolved in a pint of alcohol, with enough lamp-black added to make it the desired dark shade, will supply enough varnish to transform the pine table into a fashionable ebonized one, as the legs only require to be varnished. Then cover both shelves with dark blue or olive plush or velvet, which can now be purchased very cheaply, and put a straight valance of the same round the lower shelf. Finish the top one with a worsted chenille fringe, in bright Persian colors, and edge the valance with the same. It will take only about a yard and a quarter of the plush, and three yards of fringe; and your table will be the admiration of all who see it. If it is to stand against the wall, three sides of the lower shelf only need be trimmed, and the drawer left for use at the back.—For a bedroom these tables are pleasing, if simply varnished and covered in the same way with a pretty, cheerful cretonne, edged with a full ruffle of the same. Such a stand is a useful gift for an invalid, when placed by the couch, to hold bottles and glasses.

Taste in House Furnishing.

A simple room plainly and cheaply furnished, but arranged with a careful and artistic eye and hand, may be more attractive than the most sumptuous drawing-room where the divine gift is lacking. A very good test of a room, is to consider "Would it look pretty in a picture?" To find this out turn a mirror upon the different parts, and see the effect. This will often help one to correct and re-arrange anything that may be wrong. If new carpets cannot be procured, Brussels and ingrains may be wonderfully cleaned and brightened by washing them, on the floor, with white castile soap and water. This renews the carpet, never injures, and always freshens it. Take two pails of tepid water, and finely scrape into one enough white soap to make a slight lather. Wash the surface of the carpet lightly (not sopping), with the lather only. The large scrubbing brushes with long handles are good for the purpose. Rinse well with the second pail of water, still not wetting too much, and dry with soft, clean cloths. If the carpet is worn as well as soiled, cover the centre with gray linen, leaving a bordering of the carpet. This linen, too, makes excellent coverings for lounges and chairs, and a curtain of the same, washed of its stiffness, trimmed with Ritcella or antique lace, and hung on a pole, falls into most graceful folds.

The arms and legs of odd chairs may be tastily adorned with bunches of ribbon. Lace curtains are looped back with wide satin ribbon, generally white, or old gold. For bedrooms the newest curtains are of plain India mull, the same color as the furnishings of the chamber. If blue, they are tied back with pale pink ribbon, and *vice versa*. The latest portieres are of crazy patchwork, oriental in their gorgeousness and very handsome. Fine paintings are great furnishers, and she who is so happy as to possess these, should make the most of them, and have her drawing-room walls of a neutral gray to throw them out to greater advantage. But if good oil or water colors be wanting, have a paper of robin's-egg blue, with a maroon bordering, or one of the charming Morris Rossetti papers designed in naturalistic figures.

In these days, however, no one should be without good pictures of some kind, when beautiful etchings and engravings are so plentiful and cheap, and fine copies called "Photo-Gravures," of Mil-

let's "Angelus," Raphael's, "Sistine Madonna," and other masterpieces of Delaroche, Alma Tadema and Millins, can be had for a few shillings. These can be framed at home with broad strips of mahogany, that will contrast well with the creamy tint of the paper. Smaller pictures should be mounted and framed with a plush mat of olive-green, crimson, or duck's-throat blue. But do not make the mistake of overcrowding a room with ornaments, giving it the appearance of a bazaar or shop. Bric-a-brac and dainty bits of needle work give a great air of comfort and refinement, if not overdone. A touch of yellow is necessary to the beauty of every apartment, and, when possible, have an open fire, which is the very soul of home. A richly tinted jar or vase rightly placed, will often give expression to a whole room, while growing plants are always desirable. Never place natural flowers in a vessel ornamented with flowers. Goethe says "Art is called Art, because it is not Nature," and we cannot expect to bring painting, no matter how well done, close to Nature without the former suffering somewhat by the contrast.

A Scrap-Receiver from a Fan.

The scrap-receiver or catch-all seen in the engraving, is easily made from an old Japanese fan. Remove the fastening which holds the fan-sticks together at the bottom, and secure them with a strong thread. Cut away the side-pieces. Run a ribbon alternately through the loose part of the fan, and fasten it on the inside. Pass a thread through each fold at the top, and draw it to the size desired. Make a cornucopia of paste-board to fit inside the covering. Cover neatly with Silesia. Hang the receiver with a silk cord or narrow ribbon. Finish it at the bottom with a bow of broad satin ribbon. Also place one near the

A RECEIVER FROM A FAN.

top. If the ribbon employed is narrow, make many loops and ends to the bow.

A very neat covering for a flower-pot can be made of a fan, by cutting the sticks away close to its body, and running a stout thread through each fold at the top and bottom. Place the fan around the flower-pot, and tie it in position.

VIRGINIA CORN BREAD.—One quart of white corn meal, one teaspoonful of salt, two eggs and a dessert spoonful of butter. Scald the meal thoroughly with boiling water. Then add the butter and eggs (well beaten), and lastly a half-pint of milk. If this does not make the batter thin add more milk, for this is a soft-bread, requiring a spoon in serving. Bake twenty minutes in a very hot oven.

Make Your Home Attractive.

Can we do too much to make home healthful, pure, and beautiful? It is especially woman's mission to do this, and to what nobler work can any woman aspire than that of moulding the characters of the boys and girls to become the men and women who are to fill responsible positions in private and public life. We are often shown some cheap, unattractive dress, bought "just to wear at home," and a glimpse is frequently had of some wife and mother in the morning, with hair uncombed, frizzes still in papers, loose wrapper without collar or ribbon, etc. This, she says, is "well enough for home." In her afternoon promenade, stylishly and becomingly dressed, we should hardly recognize her. In these days, when a pretty print or muslin dress can be bought for five or eight cents a yard, cambric and satteens in choice colors for fifteen cents, or cotton and wool fabrics for suits at twenty-five cents, there is little reason why a lady should not be prettily dressed when about her work at home. If the warm, damp weather takes the curls all out of her frizzes, a few moments should be employed after the family are scattered to put them up again. A little more trouble and expense will more than pay, if the little children are overheard to say, "Doesn't mother look sweet?" Boys, especially, are very early influenced by the surroundings of home. Happily the old custom of having a "best room" shut up, except for weddings, funerals, or occasional company, is fast being abandoned. Now the home rooms are all thrown open. Sunbeams are welcomed, for it has been found, that it is a choice between them and malaria, or disease in some form. All the best things are not crowded into one room, and the others left bare and shabby. Doors are removed, and curtains or portières, hung on brass or stained rods, divide halls and rooms. The curtains are made of a variety of materials. There are heavy striped and figured goods, which come for this purpose, but plain goods with broad bands of contrasting color are richer. Double-faced canton flannel is the best cheap material. Dark blue or garnet is handsome, and bands of strips used for saddle-girths, or some kinds of coach trimmings, are very effective upon them. Often one wishes a curtain between a large and small chamber or dressing-room. Cretonne is best for this. Screens used for this purpose are very useful and ornamental, and may be very expensively or cheaply made. A clothes "horse" makes a good frame when stained or ebonized. If it has three panels, each should be different. Painting and embroidery are very handsome, but they are expensive in time and money. Rich wall paper with dado and frieze, if the patterns are carefully selected, make a very handsome screen. A small one of plain felt, with a bunch of peacock feathers in one corner, is pretty. Coarse canvas-work, canton matting, painted roughly, or embroidered with coarse worsteds; cretonne, with figures outlined with crewel or silk; Japanese or Chinese crape pictures with velvet borders, are some of the other designs used. In nothing does good taste in the home manifest itself so much as in the ornamental furnishing. To do without it altogether, makes a room look bare and uninviting, even if well furnished. Too much of it is even worse in its effect. A few well selected ornaments for the parlor are in much better taste than many cheap ones. Books are in place almost everywhere and pictures also, but one bad better go without the latter until they can be purchased one by one from among the best. Copies of fine paintings—engravings, can be readily found to meet the taste and purse of those who cannot afford to buy the originals. Marble topped tables, by some called "parlor tombstones," are discarded, and table covers of all descriptions are used. Bureaus are furnished with covers, pin-cushions, handsome bottles, and a jewel-case. Especially in table furnishing should the best that one can afford be provided. It used to be the ambition of most ladies to have a plated silver tea set, if they could not have a solid one. Now these are set aside, and glass and china, of which no

two pieces need be alike, take their place. This involves some trouble, for a lady must take such things into her own care, if she would preserve them, but is any trouble too much to make home more attractive? ETHEL STONE.

A Circular Flower-Stand.

For the upright center-piece of the flower-stand shown in the engraving, use a stout scantling, two by two inches at the bottom, and tapering towards the top. To this, bolt four hard-wood legs, which in shape and position resemble those seen on many center-tables. Two circular shelves about eight inches in width, are supported by four braces running through the central support. To keep the shelves firmly in place, run two stout wires across the center at right-angles. On the top of the support, place a circular shelf for one large flower-pot, or two or three small ones. The lower shelf is three and one-half inches across, and comes up to within six inches of the window sill. A railing is placed around the outside edge of each shelf, to prevent the flower-pots from slipping off. This stand will enable one to arrange plants attractively.

A CIRCULAR FLOWER-STAND.

With casters under the legs, the stand can be easily turned around, and all the plants given sufficient sunlight, without moving the flower-pots. This circular plant-stand may be quickly and easily made by any one familiar with ordinary tools.

A Cellar-Bin.

The engraving shows a cellar-bin we have used for years and can highly recommend. It is twelve feet long and four feet wide, with six posts. A bin sixteen feet long requires eight posts, four at the corners, and two intermediate on each side, each three and one-half feet long. A floor is nailed on the cross-pieces, and the sides and ends are eighteen inches high. The bin is easily made deeper by using longer posts and more siding. Use no straw, as it harbors mice. Pour in the apples and potatoes carefully, and they will not bruise. Two or more kinds of fruit or vegetables may be separated by partitions. The bins may be placed against the cellar wall, and a board laid on the top at the front, makes a convenient shelf. A bin sixteen feet long, four feet wide, and eighteen

A BIN FOR THE CELLAR.

inches deep, requires two two by four scantlings, fourteen feet long, and one hundred and twenty-four square feet of inch-boards, each sixteen feet long. A twelve-foot bin requires two two by four twelve-foot scantlings, and ninety-six feet of inch-boards, twelve feet long. J. M. S.

A Convenient Corner-stand.

A neat, serviceable, and quickly-made corner-stand is shown in the engraving. The top and shelf, *b, b*, figure 1, should be twenty inches wide. When boards of the proper width are not at hand, nail two narrow ones together with cleats on the under side. The square legs, *a, a*, are an inch and a quarter thick and thirty inches long, secured in

Fig. 1.

Fig. 2.

place by nails or screws. If the baseboard of the room projects, the legs should be fitted to it, allowing the top to press firmly against the wall at all points. Tack a cloth curtain around the top, of sufficient length to reach the floor. The stand may remain plain with no cover, be covered with oil cloth, or painted as desired. There may be two shelves below the curtain, which will be very convenient for storing small articles. L. D. S.

A "Smoke-House," or Smoke-Box.

An easily extemporized "smoke-house" is shown in the engraving. An old box-stove is placed in the back-yard, with a dry-good's box mounted on a frame close at its rear. The stove and box are connected by an elbow of stove-pipe. Place hooks in the top of the box upon which to hang the hams, etc. One end of the box serves as a door. The fire in the stove is easily governed by a draft-slide in front. An opening in the rear of the box over the door, allows the smoke to pass out when necessary; otherwise it is closed by a slide. When a smoke-house of this kind is once used, we are

AN EXTEMPORED SMOKE-HOUSE.

sure no one will thereafter willingly resort to old barrels or hogsheads, which frequently are set on fire, injuring the meat that is being smoked within.

NICE SPICED ROUND OF BEEF.—Rub the round well with a mixture of salt with one-third its bulk of saltpetre; let it stand two days and wash it off. Then for fifteen pounds mix well together a pint of salt, half pint brown sugar, half tablespoonful of red pepper, half ounce each of cloves, mace and allspice, with a teaspoonful or more of saltpetre according to its purity and the high red color desired. Take out the bone and rub the spice mixture all over, inside and outside. Put in a crock or any earthenware vessel that will about hold it, and turn and rub well with the mixture daily for ten days. If the exuding juice does not cover it either make brine enough out of the same materials to cover the whole, or turn it over every two days for three weeks, when it will be ready for use. Stew it slowly all day in its own liquor. Then pack in a vessel that just holds it, with a heavy weight upon the cover during a night.

BOYS & GIRLS' COLUMNS

At the Ferry.

Down the woodland path comes Queenie, pretty Queenie! with her bonny brown eyes and fair waving hair! the purple haze of the summer twilight enwrapping her as with a mantle, and the last rays of the setting sun glancing o'er her white dress, pale cheek, and the gay-hued flowers she is carrying to grandma, who lives in the old red house just across the river. The sleepy birds twitter a happy lullaby in the tree tops, the water-lilies float calmly on the rippling stream, and all nature seems to rejoice at the evening hour. As Queenie reaches the little rustic pier jutting out into the river, she takes a small whistle from her pocket, and sends a clear, sweet signal ringing across to the old boatman, to come and row her over the ferry. A sad, dreamy look creeps into her dark eyes, and the droop of her rosy lip shows that her thoughts are not all without alloy, for "the thoughts of youth are long, long thoughts!"

"If it were but Ronald coming to row me over," she sighs, as memory flies like a white bird to the friend and playmate of her earliest years; the brave, handsome lad, who twelve months before had left his country home, and gone to seek his fortune in the great city. "How happy we were together! and what merry rambles we had in the green-wood, and what pleasant sails on the dear, old river! The ripest berries and brightest leaves were all for me, and together we sought the nest of the earliest birds, and the sheltered nooks where the May flowers first breathed forth their spicy fragrance.—Sweet little secrets, dear to our childish hearts! How Ronald always teased old Carl to let him row me across the river to school, and how we annoyed the old man by lingering on the way, to gather the great golden-hearted lilies, or watch the tiny fish dart through the blue water! Sometimes he was 'Prince Charming,' and I his 'Lady Fair,' whom he carried away to his beautiful castle in Fairyland; and he would heap a wealth of wild flowers at my feet, and crown me with a wreath of woven oak leaves. He always ended the play by saying, 'Just wait, Queenie, until I am a man, and you will see what I can do,' and then bending to the oars while I reclined in the stern of the little boat, he sang merrily,

'And jewels so fair, you shall twine in your hair,
And a lady you'll surely be.'

While I laughed, and pelted him with pink and white laurel blossoms, telling him I was quite con-

tent to be plain little Queenie, so long as he came to row me over the ferry. But, ah me! I fear he will never come again, for it is six long months since a word has come from that big, cruel town, that has swallowed up my bonny, golden-haired, little boatman; and there is none but crabbed old Carl to row me across. Now I never loiter by the way, but hasten as fast as ever I can," and something that glistened like dew-drops fell upon flowers she was carrying to her dear grandma.

The gray shadows deepen and darken, and Queenie has to strain her eyes to catch a glimpse

Jack, the Bridge Mouse.

S. C. A.

"Mary, we are to have a visitor next week; I forgot to tell you before," remarked Farmer Ellis, as having finished his supper, he leaned back in his arm-chair, and smiled contentedly on his wife at the other end of the table.—"Who?" asked Mrs. Ellis in some surprise, and "Oh! pa, who is it?" exclaimed three eager childish voices.—"I don't know his name," said the farmer, "but this after-

noon I met the minister, and he asked if I would entertain one of the children sent out by the 'Fresh Air Society' for a couple of weeks."—"But you did not say yes?" cried his wife.—"Of course I did! Why! I should be ashamed to refuse a poor little chap a home and glimpse of the green fields for a few days."—"Yes, but think of the association for our own children," and Mrs. Ellis glanced anxiously at the bright, innocent faces round the board. "These boys and girls come from the lowest slums of New York, where they must see all forms of misery and wickedness."—"The more reason why we should do them good when we can, and give them a happy time while they are with us," said the kind-hearted farmer, "and I hope Harry and May will take pains to be very kind to the poor little one, whoever he is."—"Yes, indeed we will," cried the two elder children, whose sympathies were easily enlisted, while four-year-old Lilly, the baby and pet of the household, nodded her golden head, lisping, "and me too! me show poor 'little boy my kittens!" for a trio of gray and white kittens housed in the woodshed were at present her dearest treasures.

As it seemed settled, Mrs. Ellis made no further objection, but she felt many misgivings about letting this black sheep in among her carefully tended flock; although her motherly heart was filled with pity for the wretched little waifs, whose one bright spot in the whole year is their fortnight spent in

the country. So five days later, Harry and May stood one fine summer evening on the platform of the little railroad station, eagerly watching for the incoming train that was to bring them "their boy," as they liked to call him. A visitor of any kind was a rarity in their quiet home, and they had planned all sorts of fun and frolics for the next two weeks. It came at last! the iron horse steaming and puffing like some monster in distress; and from the long line of cars alighted such a bevy of little folks, in shabby though neat clothing, wearing the blue ribbon badges of the Society, and with eager, expectant faces, that the children were quite puz-

WAITING AT THE FERRY.

Drawn and Engraved for the American Agriculturist.

of the little boat now bounding toward her from the opposite shore. "Old Carl's rheumatism must be better," she thinks, "for he never rowed so fast before," and she prepares with a sigh to clamber down by herself into the rickety little boat, for the ancient ferryman is anything but gallant. Nearer and nearer it comes, and the girl covers her eyes with her hands, to shut out the wrinkled old face, if only for a moment, but—is she dreaming? A merry laugh sounds in her ears, her hands are pulled quickly down from her eyes, and a happy boyish voice cries: "Will you not look at me, Queenie? I came back to row you over the ferry."

zled. "Which shall it be?" whispered May in despair, as she viewed the group, of all ages and descriptions. But there was little time to choose, for the hospitable farmers and their wives had flocked from all the country round, and were speedily selecting their guests.

"That is a fine looking boy," said Harry, pointing toward a lad about his own age, in a torn straw hat, who was bidding "good bye" to a little girl, and without more ado, he stepped forward and said, "will you come with me!"—It was a bright sunny face that turned to meet him, and a pleasant voice that gladly assented, while the little street Arab showed a sort of rough courtesy in the way he pulled off his ragged hat, as his young host said, "this is my sister May, and I am Harry Ellis."—"My name is Jack Carter, but the fellows generally call me 'Bridge Mouse.'"—"Why?" asked May, opening her brown eyes in surprise.—"Oh! cause when the papers don't go off sharp, I mostly sleeps round the Brooklyn Bridge; and some first-rate places there are under the arches, too."—"Are you a news-boy?" asked Harry.—"Yes, I cries 'Tribune, World, and Eve'nin Telegram' for a livin', and when times is good, a collision on the Elevated, a panie, or anything lively, I jest live in clover, git a fifteen-cent dinner, and put up at the News-boys' Home, in style. But is this the real, true country."—"Yes," said Harry, "and old Peter is waiting to take us home to supper," and he led the way to the two-seated wagon, drawn by a steady-going white horse, in which they were soon rattling briskly over the road toward the Ellis homestead; while Jack kept Harry and May in continual bursts of laughter by his quaint remarks.—"How good it smells," he exclaimed, as he inhaled the air, sweet with the odor of clover and new mown hay, "jest like a big Washington Market 'bokay.' Who owns all them flowers?" and he pointed to a great field of yellow and white daisies.—"You and I as much as any one," laughed Harry, "they're wild."—"Really! oh! how I wish Dickie could see 'em, he loves posies so. Dickie is my brother, and blacked boots till he was run over one day, and took to the hospital; but won't the p'lice he after yer if yer go on the grass?"—"No indeed, there are no policemen here."—"It's a heap nicer then, than Central Park, for the cops is allers a tellin' yer to move on, jest as though there was any place to move to."

So gaily chatting, they felt very well acquainted before the farm-house was reached, where Mrs. Ellis stood in the doorway, and little Lilly came running down the path, holding up an apronful of wee pussies as a token of welcome. It was many a day since Jack had sat down to so hountiful a meal as awaited him that evening, and Mr. Ellis said "it did him good to see the way the boy enjoyed his brown bread and berries."

"Is this milk?" he asked, as a creamy glassful was set before him. "It tastes more like butter, New York milk is blue."—"I guess the pump is their best cow then," laughed the farmer, "but go out with Harry, and see what our little Alderneys can do." Jack accompanied his new friend to the yard and watched with wonder the streams of rich milk that fell foaming into the bright tin pails.

"Are they milk all the ways through?" he asked, as he ventured to pat one of the mild-eyed kine, at which question Harry almost rolled on the ground with merriment.

"What a lot of canary birds, too!" he cried, as a brood of tiny, golden chickens hurried by, in the wake of a mother hen; "do they all sing?" and was greatly surprised to learn that these fluffy yellow balls, were only baby fowls.

But in some things Jack was very bright, and when the lamps were lighted, he entertained the family with funny stories of city life; and keen, shrewd remarks, greatly to the amusement of Mr. Ellis, who delighted in drawing him out. Lilly was attracted to him at once, and the two soon became warm friends; the little one trotting after him wherever he went, while Jack was always ready to carry the wee lady through the woods, or play games with her on the smooth lawn. It was a happy time for the little newsboy, and he grew

fat and rosy, while Mrs. Ellis never had cause to regret his coming into her household. What picnics they had in the shady, green woods! what frolics in the hay-field! what fishing and swimming in the creek! and what jolly rides behind old Peter! It seemed to Jack that the days fairly flew away, until at length, the last one had dawned, waxed and waned, and he sadly packed his little carpet-bag, to which Mrs. Ellis added a suit of clothes belonging to Harry, who himself brought a collection of fish-hooks, lines, and birds' eggs, and other things dear to the boyish heart. May came with a plate of cakes and tarts of her own baking, and little Lilly toddled in with a great hunch of buttercups and daisies, for "poor Dickie in the hospital," of whom she had heard many interesting tales.—"Wonder if Mother Bridge will be glad to see me back," said Jack to himself, as he tumbled into bed, "but I know she won't give me as soft a pillow as this."

Regret, however, could not keep such a hearty, tired boy awake, and he slept soundly, until aroused by a confused murmur of voices, and a sense of suffocation. He sprang up, and was startled by a lurid light, while the dread cry of "fire! fire!" fell upon his ears. He hurried on his clothes, and then groped his way through clouds of dense, black smoke, down to the ground floor, and out upon the lawn. Here he found the family and neighbors running hither and thither in mad confusion, while the flames shot heavenward, and the house seemed to wither beneath their fiery tongues.

"Are all safe?" asked Jack of Harry.—"Yes, mother and May are just over there."—"But where is Lilly?"

At that moment a loud cry arose, and looking around, Jack saw every eye fixed upon an upper window, where now appeared a golden head, while two white arms were outstretched beseechingly, and a piteous voice cried, "Mamma, mamma!"

It was too evident that in the confusion and fright Lilly had been left asleep in her crib, each parent believing her with the other. With a groan, Mrs. Ellis darted forward, but was held back by many hands, as every instant the roof was expected to fall. "A ladder! a ladder!" was the cry, and several started in search of one.—"They will be too late!" exclaimed Jack, and throwing a blanket over his head, he boldly dashed into the building.

It seemed ages to the spectators before the news-boy succeeded in reaching Lilly's side, but once there, he appeared to know just what to do. He had too often followed the engines, and watched the brave firemen, to be at a loss in such an emergency. Pulling the sheets from the bed, he tore them into strips, knotted them quickly and securely together, and then tied one end around the little girl's waist.

"Now be ready," he shouted, as lifting the child to the narrow ledge, he began gently to lower her towards the ground.—"Oh! Jack, I'm afraid," cried Lilly, "you come too."—"Yes, darling, presently," but just as the little one was clasped in loving arms, a loud crash sounded on the night air, a rush of flame and smoke obscured the scene—the roof had fallen, and the young hero, where was he? Not dead, fortunately not dead, though many thought him so; when a ladder being brought, the men ascended and carried down the senseless and blackened form of the poor little "Bridge Mouse," for although stunned, he was not crushed by the falling timbers, and he had fallen across the window, where a little air saved him from suffocation. But he was badly injured, and for weeks he lay weak and helpless in a neighbor's house, carefully tended by Mrs. Ellis and May, who could not do too much for the preserver of their darling Lilly. And at last, slowly and painfully, he came back to life and strength; but when he walked out for the first time, he found the leaves turning to russet and gold on the trees, and the frame-work of a new house rising on the charred site of the old one.

"Mother Bridge will think that I have deserted her," he said with a little sigh, "but I shall soon be able to go back now."—"Not if you prefer to remain," said Mr. Ellis, "we would like to keep you with us, and the home you have saved from deso-

lation, is your's, if you choose to stay, for we feel we can never repay you."—"Oh! thank you sir," cried Jack, while a radiant smile of delight flitted over his face. It was, however, succeeded by a cloud, as he hesitated, and then said slowly, and with an evident effort, "But I couldn't leave poor Dick. I am all he has in the world, and he needs some one to fight for him, now he's lame, and to cheer him up. I'd love to stay, but I must go back to New York and Dick." Tears however filled his eyes, and Mr. Ellis, too, had to wipe his spectacles, and turn aside to hide his emotion, for he fully appreciated the boy's sacrifice for his afflicted brother. So Jack returned to the City, but not to his old life, or his bedroom under the Bridge. Mr. Ellis secured him a position in a store, that placed him in comparative comfort, while he and Dickie have a standing invitation to spend every summer at Ellis farm, where Mrs. Ellis is now always ready to receive any number of city waifs. She says you can never tell when you may entertain an angel unawares.

The Doctor's Talks.

One of my young friends finds a great many shells of fresh-water mussels or elams, and wishes me to tell something about these and other shells.

Fig. 1.—A FRESH-WATER MUSSEL.

I have never seriously taken up the study of shells. I once heard Agassiz say that one "could learn no more about the animals from studying their shells than he could about people from a collection of their cast-off great coats." The great naturalist had no very high opinion of those who made collections of shells merely because they were rare and valued their specimens according to the prices they paid for them.

THE FRESH-WATER MUSSELS.

These, also called elams, are common in rivers, ponds, and lakes, and their empty shells are frequently to be found along the shore. You know that the shells of snails are all in one piece, while the shell of the mussel is in two parts, or valves, hinged together at one edge. This difference in the shells is accompanied by as great a difference in the animals that they cover. Shells like those of the snail, are called univalves, while those of the

Fig. 2.—THE MUSSEL ANIMAL.

mussels, being in two pieces, are called bivalves. In the snail the animal has a prominent head, but in the mussel the head is so indistinct that it can hardly be made out, and the animals are said to be acephalous, or headless. If you have a live mussel, or a pair of shells still held together, you find that they are united by a hinge of a dark-brown substance that is elastic, and when dry is hard and brittle. This hinge is barely shown in figure 1. The light spot at the left of the hinge is called the "beak" (*umbone*). This was the starting point in the growth of the shell, but later it often gets worn away. The lines upon the shell show the different periods of growth; they all start from

the beak. Holding the shell with the beak from you, the end of the shell farthest from you is the forward end, and that nearest to you is the hind end, while the half shell at your left and right hand will be the left and right valves. If the live mussel be placed in a basin of water, after a while there will be projected from its forward end a whitish, fleshy body, *a*; this is the foot of the mussel, and by its aid the animal moves through the sand, making a strong mark or furrow. These marks are often seen in the sand, and the mussels may usually be found by following them. If all is perfectly quiet, the shells in the basin will open a little, and at the rear end will appear a little fringe, *b*, *c*, figure 1. If this is carefully watched you can see that this fringe surrounds two openings; by

his knife and the shells may be readily opened. To open the mussel, these two muscles must be cut.

"DIAMOND STONES."

Lennie J. Rowell, Kans., sends me several small crystals which he says, from their shape, are called "diamond stones." They are flat plates, rhomboidal in shape, and from the thirty-second of an inch to half an inch across. He properly notices that the stones "are all of the same bevel," and says: "Please explain these things."—The crystals are of a dull flesh color, when held up to the light are partly transparent. By reflected light they have a pearly lustr. As to explaining these things, that is impossible. We can only accept them as a part of the great order of nature. Minerals when

to be so in the countries named. We present herewith an engraving of the snake-charmers who are frequently seen in India.

The snakes shown in the illustration are very different from any found in this country. The Portuguese gave to the species the name "Cobra de Capello," a snake with a hood, or hooded-snake. The creature, a native of the East Indies, is able to stretch out that portion of its body just below its head in the manner seen in the engraving; it does this when attacked or excited in any way, and can raise itself to a more or less erect position, supporting its body by means of the tail. Its appearance is then threatening, and it is not surprising that the natives have a great fear of the serpent, especially when its bite is often fatal? The

A GROUP OF EAST INDIA SNAKE CHARMERS.

Engraved for the American Agriculturist.

the motion of small particles in the water, it will be seen that a current is steadily passing in at the lower and out at the upper orifice. The current carries in animalcules and other kinds of food, and as it passes over the gills of the animal, supplies it with breath from the air dissolved in the water.

The animal itself is shown in figure 2, in which the right-hand valve or half-shell is removed. Within the shells, and lining them, is a thin membrane called the "mantle;" this is indicated by the lines running towards the lower edge of the shell and increases its size. The surface of this mantle next the shell provides the pearly substance that lines it. We see here, the foot, and at *b*, the fringe around the openings already described. The largest object within the shell, marked with strong cross lines, is the gills. The mouth is at *a*, a queer place for it, just above the foot. In this figure you have a better view of the ligament, *l*, that hinges the two valves together. The tendency of this is to open the shells. The animal holds them together by two strong muscles attached at *a*, *a*, and passing to the other shell. When these muscles are relaxed, the shells spring apart. In the oyster there is one such muscle, incorrectly called "the eye." The oysterman cuts this with

pure have definite forms, a peculiarity stamped upon them by the Creator, and which allows each mineral to be recognized. The crystals sent are Felspar. A very common and important mineral, and one which presents a great many varieties. It forms a large part of the valuable granite rock.

Snake-Charming.

Showman and snake-charmer, James Reilly, became careless while exhibiting his three Diamond-back rattlesnakes at High Bridge, Upper New York, a few days since, and was stung by one of them. He died in the New York Hospital, repeated large doses of whiskey proving unavailing. Very frequently, from Pike County, and other portions of Pennsylvania, cures of rattlesnake bites by whiskey are reported, and it is generally supposed to have been regarded as an antidote for rattlesnake poison, when taken in time. The death of Reilly shows, however, that it cannot be relied upon. The common treatment in Australia and India for the rattlesnake is the injection of ammonia into the veins of the arm. While we are unable to assure our readers that this is an antidote and cure, it is believed

snake is between three and four feet long; its general color is brownish-yellow. The hood has various markings of white and black; these are said to sometimes resemble spectacles, as seen in the central reptile in the picture. But what are the snakes doing in the baskets, and what have the men to do with them? The jugglers in India claim that they are able to charm the reptiles, and render them harmless, and snake-charming, as it is called, is a popular exhibition. The jugglers go in parties from place to place, carrying the snakes in baskets. When they are charmed by the music, the reptiles are handled without attempting to bite. All this is very wonderful to those who do not know that the Cobras have had their poison fangs extracted. The many books of travel in India give accounts of these exhibitions of the snake charmers. Some writers state that the performers, by skill in handling the reptiles and agility in avoiding their attacks, escape injury. Others, on the other hand, assert that the jugglers admit that the fangs are removed. The serpents are trained to move in time with the music, and perform a sort of rude dance. The snake feeds upon frogs, toads, and other small animals, and often enters houses in search of rats.

Milk, Butter, and Beef.

Here are two famous cows. The butter-maker, figure 1, is of the highest type of excellence. A native of the little Island of Jersey, dropped in January, 1881, she closely approaches perfection in every point. Her head and forequarters are neat and deer-like; her disposition, as shown by the full, mild eye, is quiet and passive; her constitution, as indicated by erect carriage, straight back, deep and broad chest, broad loin and low flank, is good. Her capacity for food is great, as shown by her capacious paunch; and withal, her excellence as a milk-yielder, is indicated by the full development of the hind-quarters, the perfection of the udder and teats, and the conspicuous milk veins upon the abdomen. The promise thus given in her form has been carried out, for as a three-year-old she made sixteen pounds fourteen and a half ounces of butter in a week, and has been doing still better since. This cow was imported less than a year ago by Mr. T. S. Cooper, of Pennsylvania, as Fill-pail 2d, with her dam, Fill-pail, both cows of extraordinary excellence, and deep in the famous blood of Welcome and Coomassie on the side of her sire.

Mr. Cooper has won great fame as an importer, and for investigating pedigrees on the Island. American Jersey breeders owe him a great deal for the work he has expended upon island pedigrees, without which we really would not have known much about the blood sources of many of the popular modern strains, beside the little that is given in the herd-books. Fill-pail 2d was recently sold at auction for a high price.

The other portrait is of the famous Hereford cow, Leonora. The Herefords are one of the typical beef breeds of England, and while Shorthorns are claimed as valuable for both beef and milk, and among the Devons great milkers are not rare, and good milkers and butter-makers are the rule, the Herefords are in comparison nearly worthless as milkers, and famous for rapidity and economy with which they lay on flesh, and for their nearly perfect and economic form. The muscles are developed just where the meat brings the highest price, and the fat laid on with that characteristic evenness, which marks the most perfect beef animals. This is a peculiarity rather of the individual than of the breed, and yet more often found among Herefords than among animals of any other breed. The reader will note the general length, fullness and evenness of the carcass, the squareness of the hindquarters, the depth and prominence of the brisket, and the remarkable level character of the belly-line. The breadth of the back and loin is indicated rather than seen, but the enormous length and breadth of the thighs, the masses of flesh over the ribs, the delicacy of the bone, and smallness of what in butchers' parlance is called offal, are most conspic-

uous. "Offal" is all except the tallow and hide which cannot be disposed of on the market stand. This includes the head, tail, feet, and viscera. It is easy to see that if these parts were removed, the carcass would present an almost solid mass of beef.

American farmers need to make their selection between the beef breeds, the milk breeds, or those which combine both milk and beef. Whether it is

"FILL-PAIL 2D," A COW FOR MILK AND BUTTER.

Re-engraved from *Agricultural Gazette* (London) for the *American Agriculturist*.

better to turn a certain amount of fodder and grain into butter, or cheese, or beef, will really depend upon the condition of the market. Where there is a good market for milk, the highest profit is in that. Outside the milk range, the market is for butter or cheese, or both. This involves labor, but the labor is usually well rewarded. Beyond the labor line, where milk cannot be manipulated, it must be used for raising calves, and the chief product of the farm or "range" must be beef. The beef of the plains forces down the prices of common beef throughout the country, even though it has the disadvantage of thousands of miles of transporta-

The Pig as a Plowman.

Farmers everywhere are influenced by the construction of railroads and other means of quick transportation, but none of them more so than those who grow meat as a branch of their farm operations. The pork-raisers in the older States come in competition with the swine products of the prairie

States, where the pig is a condenser of the corn crop, and among the most economical methods of sending that cereal to market—yet even with cheap freights, it will not do for Eastern farmers to abandon the sty, and look to the West for their salt pork and hams. There are economies to be practiced in swine raising that will make the Eastern farmer successful in his competition with the West. He has the protection of freights over long distances, which can never be very much reduced. The home market will always be remunerative, so long as pork products are in demand. His lands need manure, and that which is made in the sty, and under cover, is among the best of the home-made fertilizers. Herding swine upon pasture, or old meadow, that needs

breaking up, is not very much practiced, but is one of the best methods of raising pigs. They are as easily confined within a movable fence as sheep, utilize the grass and coarse feed quite as well, and perform a work in stirring the soil that sheep can not do. The nose of the pig is made for rooting, and we follow nature's hint in giving him a chance to stir the soil. A movable yard, large enough to keep two pigs, can be made of stout inch boards, about fourteen feet long, and six inches wide. For the corner posts use two by four inch joists. Nail the boards to the posts six inches apart, making four lengths or panels four feet high. Fasten the

corners with stout hooks and staples, and you have a pen or yard fourteen feet square, which is easily moved by two men. If you place two fifty-pound pigs into this yard they will consume nearly all the grass and other vegetation in it, in three or four days, and thoroughly disturb the soil several inches in depth. When they have done their work satisfactorily, the pen can be moved to the adjoining plat, and so onward through the season. The advantages of this method are, that it utilizes the grass and other vegetation, destroys weeds and insects, mixes and fertilizes the surface of the soil about as well as the ordinary implements of tillage. In the movable

"LEONORA," A COW FOR BEEF.—Re-engraved from *Agricultural Gazette* (London) for the *American Agriculturist*.

tion, more or less. Hence it increases the importance of dairy interest, and of dairy cattle. The uses of cattle determine their characteristic form. In judging of dairy cattle at shows, it is absurd to allow fatness to warp the judgment. Milk is the criterion—ability to produce milk or butter, while in passing upon the beef animal, the judge must look to beef points, ability to lay on fat evenly, early maturity, and the development of the choice parts. It is not an easy thing to judge a beef animal.

yard there is thorough work. Even ferns and small brush are effectually destroyed. Worms and bugs are available food for the pig. And it is not the least of the benefits that the small stones, if they are in the soil, are brought to the surface, where they can be seen, and removed. The pig's snout is the primitive plow and crow-bar, ordained of old. No longer jewel this instrument, but put it where it will do the most good, in breaking up old sod ground, and help make cheap pork.

Editorial Correspondence.

From the North-west.

Abundant Harvests.—The golden horn of plenty is pouring in its richest treasures upon our land. Wherever we have gone, through Ohio, Michigan, Illinois, Iowa, Wisconsin, Minnesota, and Dakota, we have found the tillers of the soil happy in the prospects of luxurious crops. Here corn has suffered from the drouth; there hail stones as large as walnuts,

"OVER THE PRAIRIE GOING."

have cut down the standing corn, or a sweeping cyclone has leveled entire fields of grain. But these are exceptional cases. An enormous wheat crop will be harvested, and if no untimely frosts, as last year, overtake the North-western cornfields, they will give satisfactory yields. While those engaged in commercial pursuits have complained, and are still complaining, of the general dullness, the tillers of the soil are apparently vouchsafed overflowing granaries.

No "Emigration Boom" this Year.—The wonderful emigration to Western Minnesota and Dakota during 1882 and 1883 apparently spent itself last autumn, and the remarkable scenes which a year ago quite took one's breath away, are not witnessed this year. The cold winter, "hard times back East," and the failure of the railroads to advertise the country as much as usual, are among the various causes assigned by the settlers for this halt in emigration, when there is still much land to be had. But we infer, as above stated, that the boom in this direction spent itself for the time being; and now during 1884 there is considerable migration to Oregon, Washington Territory, and to Western Nebraska. Notwithstanding this lull Dakotaward, there has been a steady, healthy growth during the present spring and summer, and we shall subsequently describe in detail the various villages, scattered along the network of the Milwaukee & St. Paul Railroad System, having last autumn visited and described those on the lines of the Chicago & Northwestern Railroad, as far west as the Indian Reservations, beyond the Missouri River.

Few Settlers Returning.—Ten years ago, when the dazzling stories told in the circulars of some of the railway companies, and elsewhere, allured many people from the older States to the Far West, without sufficient funds, great suffering ensued. Then scorching drouths and grass-hoppers sent thousands of them back to their old homes, broken in spirit and poverty-stricken. Now, with a better knowledge of what is required, people are not disposed to migrate to the North-west without sufficient funds to tide them over the first year or two. Furthermore, there have been but few drouths and fewer grass-hoppers these later years; but yet there are those who have returned because of the severe hardships they experienced during last winter in Dakota. Those must have indeed been trying times for the settlers in some portions of this vast territory, when the snow at times completely enshrouded their rude dwellings. But these experiences and vicissitudes the settler must expect. If he is not willing to encounter them with a stout, brave heart, he had better not go West. If, however, full of resolution, pluck, and determination, he goes to the front and surmounts these earlier difficulties, a few years, at the longest, will place him at a point of prosperity which perhaps he could not have attained in a lifetime further East. Push and patience be your motto.

Too Much Free Land for Individual Settlers.—"I think it would be much better if the Government gave but one hundred and sixty acres of land to every settler," said Mr. E. Martin, an old subscriber to the *American Agriculturist*, living near Manchester, Iowa, as we rode eastward from Mitchell, Dakota. "I would," he added, "allow no man to have over one hundred and sixty acres, and I would then compel him to put ten acres of this land in timber. Then I would exempt these ten acres from taxation. I would repeal the Tree-Claim Act, and the Pre-emption Act entirely. This would give each man only one hundred and sixty acres, which he could cultivate well, and would remove the temptation to him to get under the various Acts, too much land which he does not half cultivate. He would likewise then be removed from the temptation of allowing himself to be used by speculators in 'proving up' claims for their benefit." We found these views very generally shared by farmers on the border. And this is a question worthy of the immediate consideration of Congress. Now, by means of the Homestead Law, the Pre-emption Act, and the Tree-Claim Act, a settler can secure control of many hundred acres of land, the majority of which is likely to inure to the benefit of speculators purely. But if this were not the case, the fact that one settler can now secure so much land from the Government, will necessarily prevent a large number from securing any, inasmuch as all the land of value is being rapidly absorbed. Furthermore, the residents of these Border Lands are beginning to realize that small, well-improved farms are not only more valuable to the owners themselves, than would be large sections of unimproved territory, and that the small farm system enables the population of the Border States and Territories to increase much more rapidly. If a few settlers can come into a new country, and by means of the various Government Acts, each one secure an entire section (more or less) of land, naturally only a few are required to absorb the whole region.

Waiting for the Country to Catch Up.—When a new country experiences a boom in emigration, it brings along with it doctors, lawyers, bankers, dry goods merchants, grocers, and mechanics generally. They locate at the nucleus of a village, and the land-buyers at first have generally to employ all of them in one way or another. Business is consequently brisk for them. When, however, the tide of emigration recedes, and the land-buyers have scattered to their various prairie homes and become settled, the demand for the services of professional, business and trades-people diminishes. The village becomes dull; the hurly-burly and excitement which characterized the boom, are gone, and the villagers who rely on the farmers, complain of very dull times, and begin to question whether the Far West is such a great place after all. As the surrounding country, however, begins to develop, and the virgin soil yields crops to the tillers, money begins to flow into the villages. At first it was the money brought by the land-buyers from the older States; now it is the money made there "on the spot;"—domestic money, so to speak, as contrasted with imported. It continues to increase with the increasing agricultural development of the new region, and the villages and towns regain the activity which characterized them at first; that is, such towns and villages as pull through the reactionary period and are not abandoned. Every new region experiences this transition state. The villagers have to wait for the surrounding country to catch up, as it were, and during the waiting-period it is dull indeed.

Too many Farm Implements, and too little care taken of them.—In the great North-west, as hitherto in Kansas and Nebraska, the reckless purchase of farm machinery, and the failure to properly take care of it, is frequently noted. The new comer, because he can buy his reaper and other machines on credit, purchases freely, with the confident expectation that good crops will enable him to discharge his obligations; but if the crops are not so good, and he is unable to sell as much as he expected, he frequently gets in a close spot financially. Perhaps he has no building beyond a stable for his horses. Boards are expensive. He leaves his machinery in an open lot, with no cover, exposed to all the changing weather. It often results that he can not pay for his machinery, and, furthermore, it is much damaged sooner or later. Do not go to the western prairies to farm, unless you have enough money to pay for some machinery, and enough money to construct a proper shelter for it, after the season is over. It is an oft recurring and painful sight, as one rides over the prairie, to see these farm implements lying around loose in every direction.

Prairie Chickens Abundant.—Bevy upon bevy of young prairie chickens rose to flight on each side of the track, as our train sped down through Central Dakota, from Aberdeen, among the quiet settlements. Notwithstanding the cold weather of last winter, and other untoward causes, there is reason to believe that there will be a great abundance of birds this season. Legislation is doing considerable to protect them from the merciless destruction of pot hunters, who shoot them down for the mere pleasure of telling how many they have bagged. In making a tour through Utah a few years ago, we were impressed with the severity of the game laws, and their rigid enforcement. Utah leads the Western States and Territories in this respect. D. W. J.

Trouble with the Elm Trees.

Our subscribers in Flushing, Long Island, Passaic, N.J., and at many other points, are complaining of what is described as a new and dangerous insect, which is destroying the elm tree leaves. Some of the New York City daily papers devote much space to this pest, and express solicitude as to what the new insect may be. It is, however, not a new enemy, but, on the contrary, is the Elm Leaf Beetle (*Galeruca xanthomelana*).

The Elms in the City of Baltimore, being sadly defoliated a number of years ago, the city authorities assumed that the trouble was due to the Canker-worms, and provided the trees with barriers of oil around their trunks. The insect causing the damage was not the Canker-worm, but the larva of the Elm Leaf Beetle, and the oil could no more keep this from the trees, than the sparrows, as both male and female insects have wings and can fly. The mature insect is a small beetle, a native of Europe, from which country it was introduced many years ago. It has become wide-spread, and is found in numerous localities as far north as Newburgh, N. Y., if not beyond.

The beetles are oblong-oval, about a quarter of an inch long; grayish-yellow, with three small black spots on the thorax, a broad black stripe on the outer edge of the wing covers, and a small oblong spot near their base. The larvæ are thick, cylindrical, six-footed grubs, which feed upon the under surface of the leaves, eating out the green pulp, and leaving the hard veins as a complete

ELM LEAF AND LARVÆ OF ELM BEETLE.

frame-work. The engraving shows an eaten elm leaf, and two "worms," natural size, and an enlarged larva of the beetle on the right of the cut.

As to its destruction, the Elm Leaf Beetle has not received that attention that its importance demands. No better remedy has been suggested than showering the foliage with a very dilute mixture of Paris Green or London Purple in water. A tablespoonful of either poison in a barrel of water, would probably be sufficient, if the mixture is kept well stirred to insure a thorough diffusion of the heavy poison. Pyrethrum invariably kills them.

Color Your Butter.

Farmers that try to sell white butter are all of the opinion that dairying does not pay. If they would use Wells, Richardson & Co.'s Improved Butter Color, and market their butter in perfect condition, they would still get good prices, but it will not pay to make any but the best in color and quality. This color is used by all the leading creameries and dairymen, and is sold by druggists and merchants.

BULBS

for Autumn planting is ready for mailing to applicants.

LILY OF THE VALLEY PIPS

FOR FLORISTS, A SPECIALTY.

H.W. JOHNS'

ASBESTOS

ROOFING.

The Asbestos Roofing (with white or light gray fire-proof coating) is now in use in all parts of the world, and is the only practical and reliable substitute for tin and other metal roofing. It is intended especially for Factories, Foundries, Warehouses, Railroad Buildings, Bridges, Car and Steamboat Decks, &c., and is adapted for Steep or Flat Roofs in all climates. It costs only about half as much as tin, can be easily applied by any one, and is the only portable Roofing which has stood the test of time and the elements.

PITTSBURGH, Pa., Nov. 4, 1880.

Dear Sir,—The Roofing put on at Rochester five (5) years ago is good yet, though nothing has been done to it since it was applied.

Yours respectfully,

W. K. BOGGS & CO.

GAUTIER STEEL DEPARTMENT, OF CAMBRIA IRON CO.,

JOHNSTOWN, Pa., June 22, 1883.

Dear Sir,—We have some of your Roofing in use, and it gives good satisfaction.

Yours truly,

LEWIS WILLIAMS, M. M.

MARINETTE & MENOMINEE PAPER CO.,

MARINETTE, Wis., June 16, 1883.

Dear Sir.—Please send us by first freight 55 squares of your Asbestos Roofing, with Coatings, Nails and Brushes complete. One of our buildings that we put your Roofing on burned a few days ago, and the Roofing on that and the other buildings worked so well that we want more just like it. Please ship immediately. Yours respectfully,

MARINETTE & MENOMINEE PAPER CO.

ASBESTOS BUILDING FELT,

For interlining frame buildings, floors, &c. It is wind, dust and strictly fire-proof.

Send for Full Descriptive Catalogue, Samples, etc., etc.

H. W. JOHNS' Manufacturing Company,

No. 87 MAIDEN LANE, NEW YORK.

SOLE MANUFACTURERS of Genuine Asbestos Liquid Paints, Roof Paints, Roofing, Steam Pipe and Boiler Coverings, Plston and Wick Packing, Millboard, Fire-Proof Paints, Cements, Coatings, etc., etc.

GRATEFUL—COMFORTING.

EPPS'S COCOA.

BREAKFAST.

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately-flavored beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*

Made simply with boiling water or milk. Sold only in half-pound tins by Grocers, labelled thus:

JAMES EPPS & CO., Homoeopathic Chemists,

ANGLO-SWISS MILK-MAID BRAND.

Milk FOOD

For Infants and Invalids.

TRADE MARK.

Recommended by leading Physicians throughout the world. It consists of choice cooked cereals, refined wheat gluten, and Condensed Milk, and contains the property of diastase, which converts the starch in the Food into soluble and easily digested dextrine and sugar, when used according to the directions. It is not only **invaluable for SICK and WEAKLY INFANTS and INVALIDS**, but also the best known Food for well children. **When more well children are fed with it, fewer will become feeble.** Until the period of dentition the BEST substitute for MOTHER'S MILK is the **ANGLO-SWISS CONDENSED MILK.**

Anglo-Swiss Condensed Milk

Is the BEST and CHEAPEST

FOR GENERAL USE,

And has a LARGER SALE than all other brands combined.

ANGLO-SWISS

Chocolate & Milk
Cocoa and Milk
Coffee and Milk

Convenient & Economical.

33 Million Tins of these goods sold in 1883.
SOLD BY DRUGGISTS AND GROCERS GENERALLY.

PATENTS.

Attorney's fee contingent on Success.
Address E. H. GELSTON & CO.,
Washington, D. C.

HAVERFORD COLLEGE, PA., 9 MILES from Philadelphia, on the Pa. R. R. THOMAS GILLES, LL. D., Pres. Under care of Society of Friends. Classical and Scientific courses. Application for admission may now be made. For catalogue address Prof. ISAAC SHARPLESS, Dean, Haverford College, P. O., Pa.

Martin Amber Wheat!

This new variety of wheat has proven very satisfactory to all who have tried it, and was awarded the **first premium** at the State and county fairs in 1880-81-82-83, and stands at the head of all other varieties of wheat in the Agricultural Reports of Pennsylvania of 1882. The surest way to get the pure wheat is to send to the originator, **WM. J. MARTIN**, Catawissa, Columbia County, Pa., who now offers it at **\$2.50** per bushel, and warrants it **free from cheat, cockle, rye and other impurities**. Be careful to write your name and address plain **on Cash with order.**

FOR the purchase of the best **NORTHERN DUTCH BLACK CATTLE**, apply to **M. JONGES & CO.**, Proprietors and Commission Merchants, **Villa Sweet Home, Alkmaar, Holland.**

BUY THE CHAMPION AUTOMATIC APPLE PARIER, CORER, AND SLICER. Requires only six turns of the crank to an apple. Price, **\$1.00**. Lay aside those that take twice as long. For paring only buy the **"TWO-KNIFE" TURN-TABLE PARIER**. Requires only two turns of the crank to pare an apple. Sold by Hardware dealers. Made by **READING HARDWARE CO.**, Reading, Pa.

THE DODSON MILL.

Every Farmer and Lumberman his own Miller. **THE DODSON MILL** is acknowledged to be the most perfect and complete mill in the market, embracing cheapness, durability, and perfect work, with little power. Parts easily renewed. Send for circular.
LOUIS WALTER & CO., 53 Beaver St., New York.

FOOD

THE only perfect substitute for Mother's Milk. The most nourishing diet for invalids and nursing mothers, keeps in all climates. Commended by Physicians. Sold everywhere. Send for our Book on the Care and Feeding of Infants.
DOLIBER, GOODALE & CO., Boston, Mass.

Mesmerism Did It!

If a signature is wanted by a swindler, he has only to Mesmerize his victim, and down goes his name; swindler takes his note, sells it, and all is easy. Several parties in the interior of New York State, who bought cloths and clocks which they did not want, giving notes in payment thereof, now claim that they were Mesmerized when they did it. One old lady says she "was bewitched into doing it," which we take it amounts to about the same thing. If this Mesmer dodge becomes popular, we shall be obliged to hang out our old warning.

"The Standard Jewelry Company."

A Postmaster in Fulton County, Ill., writes us that several parties in his vicinity have sent money to the "Standard Jewelry Company," in New York City. That the money reached its destination is shown by the return registry cards, but no jewelry, "Standard," or other, has been received in return. This "Company" is said to be composed of former clerks of the notorious Tiffany & Co. It will be recollected that the business of that concern was so large they could not possibly fill the orders, and they sold out. The purchaser found he had made such a bad bargain, that he got rid of the business by making an assignment.

"Cash Paid for Stories, Sketches, Etc."

Is the purport of an advertisement that appeared in Eastern magazines and journals of good standing, from a party in a Western city. A young lady, in Plymouth Co., Mass., forwarded her Mss. In a few days a letter came from the advertiser, very elaborately stating, that the Mss. "is really very good, only it needs a little revision," to make it acceptable to the hard-to-suit editor. Ten dollars is mentioned as the price asked for the revision, but a buyer stands ready to take it at sixty dollars as soon as revised, who will not take it at any price unless it has been, etc., etc. Young writer sends ten dollars. Neither Mss. or money are heard of again. The advertiser sets his trap for another victim. It does not appear to occur to either party, that a very simple way would be to touch up the story, get the sixty dollars, and forward the author fifty dollars. The advertiser would not be quite so sure of his ten dollars, if matters took that course. Writers should avoid this "Cash Paid for" chap.

Policy Playing on a Large Scale.

Policy playing, or "Poke-a-Moke," is regarded as the meanest of all forms of gambling. It has great attractions for the ignorant, who are influenced in their investments by their dreams, or by numbers they may chance to see on carts and elsewhere in the streets. Persons of this class are not likely to have much money, and Policy allows them to gamble with dimes and half dimes—in fact as low as a single cent. These small sums are staked upon certain numbers, or combinations of numbers, and the result is claimed to be decided by the numbers drawn in the Kentucky or other lottery. Of late, it is said that the drawing which decides the fate of the players, is only a pretence. There is now an imitation of the Policy game in

"THE LITTLE HAVANA LOTTERY."

The tickets in this have numbers corresponding to those on the tickets of the Royal Havana Lottery of Cuba, but the prizes being smaller, the tickets cost less than those of the original affair. The drawings of the "Royal," which it is claimed are received twice a week from Cuba by steamer, determine the drawings of the "Little Havana." This appears to differ from Policy only in the amount required to play it; tickets and halves being two dollars and one dollar. A concern in Indianapolis is sending the circulars of this "Little Havana" gambling scheme all over the Western States. It is really more pernicious than the "Royal Havana" itself, as it tempts young people by the low

price of its tickets. A parent in Ohio writes us that the circulars of the "Little Havana" were sent to his son of seventeen. The headquarters of the concern are in New York City, and the correspondent requests us to investigate "Shipsey & Co., General Agents." These people know altogether too much to be found in when wanted. They can be reached by correspondence, but no one as yet has succeeded in reaching them in person. Arrests have been made at the place, but the parties always proved that they were somebody else.

Paying for Advertising in Ponies.

To judge from the number of his letters to country editors, that are sent to us, VanRaub can not be succeeding very well in his pony dicker. He writes to the country editor:—"I desire to introduce the sale of my fancy ponies and horses in your locality. I have no money to invest in advertising, but if you will insert the enclosed advertisement six months in a good position in your paper, and call attention to it editorially, I will ship you, free of freight, one or a pair [what's a pony or two more or less?] of beautiful ponies for your wife or little folks, in the first car-load lot that goes near your place. If acceptable, insert, send copy of paper for six months, and write what kind of ponies you desire.

(Signed) B. H. VanRaub.

A very money-saving proposition is the above. The advertisement would cost from five to eight dollars in the average country paper, while the freight on the ponies would be about twenty-five dollars. One Vermont editor writes us that in spite of the transparency of the fraud, "a good many editors have swallowed the bait." VanRaub is on the safe side, as the "first car-load lot" is not likely to be soon seen rushing around in the valleys of the Green Mountains. What a pathetic picture could be made of the editors who have published the advertisement, waiting and watching for the "first car-load lot!"

A VICTIM TO A SMALL EXTENT.

LANCASTER, OHIO, July 29, 1884.

American Agriculturist:

MR. DEAR SIR: As you are exposing the fraud Byron Van Raub, I hand you my transactions with him. He got a dollar out of me, but that was all. He was quite profuse in "thanks," but I never bought any of his fine (?) ponies. Give it to him. Your columns devoted to Humbugs interest me very much.

Yours, very truly,

WM. L. MARTIN.

Preserving Eggs—The Havana Method.

BLEDSE Co., Tenn., July 30, 1884.

To the American Agriculturist.

Gentlemen: Last mail brought me the enclosed circular. Cannot tell how he got my address. When I read it, I noticed that J. W. Spencer made it quite plain where his address is. Mr. Robinson is a moving planet, and of course can not be found. The others all at letter carrier offices, and no street or number. I remarked that it looked like a fraud on the face of it. My daughter asked what it was. I said the Havana method for preserving eggs. Why, she said, the last *Agriculturist* says that it is a fraud. We looked and found it so; but do as you please about it.

Yours truly,

LEWIS BOYNTON.

The recipe for preserving eggs by the "Havana method," was originally offered for one dollar in the remarkable "Poultry Adviser" published in Ohio. Since then others have offered to send the recipe for the same price, the latest being from Branch County, Mich. That eggs may be preserved by the "Havana recipe," we do not doubt, as it is not essentially different from the lime and salt pickle we have published without any price for these many years. The important portion of the Havana mixture is lime and salt; to this are added several other articles in small quantities, and of a kind that neutralize one another. For example, Cream of Tartar (Bitartrate of Potash), and Bicarbonate of Soda, are used in the liquid. The merest smatterer of chemistry knows that these, when put together, result in Tartrate of Soda, and (neutral) Tartrate of Potash, neither of which is known to have any preservative qualities, and if they had, they are present in quantities too small to have any effect. We regard it as a fraud to sell a recipe, different only from one in general use by the addition of ingredients which do not essentially alter or improve it. Farmers and others should stick to the old lime and salt method until some better substitute is offered than this so-called "Havana Method."

Farmers Look out for "Drouth-Proof Grass."

One J. W. Walker, Franklin County, N. C., wrote to a St. Louis paper an account of "a valuable perennial grass, valuable for hay, for grazing, and its roots furnishing a beautiful supply of excellent hog food." We are told that "its roots are white, tender, from the size of a goose-quill to that of one's finger, go down three to twelve feet deep after moisture, and yield over one thousand bushels of hog-food per acre." This grass is

abundant in its roots, and not slack as to its hay. We are told it "may be cut not less than three times a year, making all the way from one to eight tons per acre at a cutting." Twenty-four tons of hay to the acre, is a good deal of hay, but this is a good deal of a country! As we read about the many bushels of roots we thought of the

WONDERFUL "GREEN VALLEY GRASS OF THE WEST INDIES."

But Walker could not conceal his science, and lets it out that his "Drouth-Proof Grass" is *Sorghum Halepense*, and the jig is up. This "Drouth-Proof," with its muchness of roots, is the "Green Valley Grass," only the picture of that had a man reading a newspaper, with his chair tilted up against a stalk of it. It is not necessary to give this grass a new name, and make a talk over it as "Drouth-Proof." It is already well known, and has been cultivated for years in some localities as "Johnson-grass" and "Means-grass." It is valuable for some uses; it has long been profitably cultivated for baling in Georgia, and is now successfully grown in Alabama, for just what it is, and it requires no cock-and-bull stories of twenty-four tons of hay to the acre, with a thousand bushels of hog-feed added for good measure. Mr. Walker is no novice in

THE WONDERFUL PLANT BUSINESS.

Mr. W. A. Garrett, Henry County, Mo., writes us, that in the spring of '82 he saw, in the "South and West" of St. Louis, a communication from said J. W. Walker, describing another wonderful plant, the Japan Clover. Mr. Garrett being interested in Walker's article, wrote him, making some inquiries. Walker sent a price-list, quoting the seed of Japan Clover at five dollars per bushel. Mr. Garrett sent seven dollars for seed. In due time a box came, the express charges on which were seven dollars more. "I opened the box and found that it contained not a seed of any kind, but was full of sand. I wrote to the sender, but never received any reply."

HERE IS A PORTION OF MR. GARRETT'S LETTER.

which we commend to those who ask us to show up this or that as a Humbug, and add: "Do not make use of my name in any manner." Mr. Garrett writes: "As he (Walker) has entered the field again, doubtless with a view to catch others, as he did me, I deem it my duty to show him up in his true colors, so that I may save some brother farmer from investing fourteen dollars in sand." Observe Mr. Garrett does not say: "I deem it the duty of the *American Agriculturist* to show him up," but "I," and "my," as if he had duties in the matter, besides that of being willing "to sacrifice all of his wife's relations."

Cautionary Signal.

"The Golden Bee Hive."

Professor A. J. Cook, the eminent apiarist of Lansing, Michigan, sounds a shrill note of warning in the Detroit "Daily Post," which should reach bee-keepers everywhere. He writes: "I am told that I use the 'Golden Bee Hive;' that he (the patentee) has sold hundreds about Lansing; that the hive will surely winter bees, etc.... I never used said hive; I do not know of one used around Lansing, and the hive so far as I know is not used by a single prominent bee-keeper in the United States." Professor Cook further states, that "any bee-keeper has a perfect right to use all the valuable features claimed for the 'Golden Hive.' The Langstroth is free to all, and would be preferred by every bee-keeper of experience to this so-called patented hive." Concerning the wintering of bees, Professor Cook writes: "When the bees are dead next spring, as they surely will be in this hive, if we have a severe winter and his directions are followed, the 'patentee' will be in his southern home, and his warrant will be utterly worthless. He says it secures more honey. This is absurd. Bees gather all they can in any hive, if given room. Every hive of this kind sold in the country is a damage.... This man, I am told, has taken four hundred dollars from the farmers around Lapeer, Mich."—It would seem from the words of a leading apiarist, above quoted, that the "Golden Bee Hive" is something for all bee-keepers to let severely alone.

The Campaign Opened.

We give special inducements to all subscribers and friends of the "American Agriculturist," who propose to raise clubs this season, and afford such facilities as will enable them to readily procure subscriptions. Please immediately write us for full particulars, addressing your letter, Subscription Department, American Agriculturist, 751 Broadway, New York.

Seasonable Books.

Practical Forestry.—By Andrew S. Fuller: Orange Judd Company, New York. One needs to read the sub-title, in order to form an idea of the full scope and usefulness of the work. That which relates to the propagation of trees by various methods, planting and caring for them until of the most profitable size for their various uses, properly comes under the head of "Practical Forestry." Upon these matters the author has a right to speak as he does from an experience of many years, which was passed through long before Forestry was regarded as an important branch of agriculture. As valuable as this practical portion of the work really is, the author has done the tree planters of the country a greater service in bringing before them, in a compact form, a complete list of all the trees native to the United States. If this has been done before, we have not met with it. Here the planter finds a list of the native materials at hand, and these are described in a brief and popular manner, which allows some opinion to be formed of their value and uses. The work, while it includes all our native trees, does not exclude all foreign species. There are some foreign trees, the value of which in this country has long been fully established, these are of course given place. Besides, there are a number of others, but little tested, which may be useful on our soil. These newer, and probably promising trees, are known to the majority by name merely. Any description or information about them is scattered through volumes not included in ordinary libraries. Mr. Fuller has done well to bring these scattered materials together, and give such information and popular description as each appeared to require. The work will doubtless supply a demand which recent conventions and discussions have created for whatever of real value that relates to Forestry. Price, post-paid, \$1.50.

Allen's New American Farm Book.—By R. L. & L. F. Allen: Orange Judd Company, New York. When a young farmer asks, if there is not a book of ready reference to aid him in his farm work; one that will tell him how much seed is required to the acre by the different farm crops; what is the best preparation of the land, etc., in short, a work that will reply to the many questions which he formerly depended upon his father to answer, we know that "Allen's New American Farm Book" is what he wants. A correspondent writes us in effect: "I was brought up on a farm, but have been so many years in mercantile business, that I find I have forgotten many things, and those I do remember are not suited to the present day. Farming is not what it was when I left it. Can you not recommend some work that will aid my recollection, and give me in brief, hints at the present methods of managing farm work?" There is but one work that will meet the wants of the merchant who has returned to the farm—"Allen's New American Farm Book." Some banker, or other city dweller, wealthy enough to have a farm as an amusement, and as a comfortable place for the family in summer, stops at the office, remarking: "Of course I am obliged to leave the management of my place to the farmer. I pay him to do that. Still I do not like to have a man in my employ ask my advice about matters, concerning which I am perfectly ignorant. Have you not a work, in which I can get some idea of what is going on upon my own farm? The other day the farmer remarked, that 'the prospect for rowen was pretty good,' and I came very near telling him, if he would attend to the farm, the boys would look after the boating. Now I want some book which gives the meaning of farm words." This man's case, which is typical rather than actual, could be best met by Allen's "Farm Book." The work was originally written by the late R. L. Allen, the first editor of the *American Agriculturist*, who was in his day justly regarded as the most accomplished among our farmers, and who united practical agriculture with scientific acquirements in a manner very rare at that time and not too frequent since. After the author's death, the volume was enlarged from time to time by his brother, L. F. Allen, long a successful farmer in one of the most fertile portions of Western New York. The work as brought down to the present time remains, as it was originally, unique in its character, and one which meets the wants of a large number of farmers. It is rarely we find so much useful information brought within the limits of a single volume. Price, post-paid, \$2.50.

The Fruit Garden.—By P. Barry: Orange Judd Company, New York. In its last revision, Mr. Barry's work has attained to greater bulk than ever before, over five hundred pages. This is another instance in which the title fails to give an idea of the full scope and value of the work. In this country, a "Fruit Garden" is regarded as an area devoted to the culture of small fruits. So far from this, this work is a treatise upon all kinds of fruit and fruit trees and shrubs grown in the country, and treated with a directness and thoroughness, rarely equalled. The tree is started from its very beginning,

raised in the nursery, planted in the orchard, cared for until it bears, when its fruit is gathered, packed, and shipped to market. Everything is openly and plainly told, and the reader has no feeling that any trade secrets have been kept back. The author believes that the best way is the best, and he gives those methods that have led to success in the most extended and varied nurseries in the country. It is just the work that each one who grows fruit, whether for home use or for market, should have at hand for reference. Those about to commence fruit-growing, will find autumn the best season in which to begin preparations. Price, post-paid, \$2.50.

Mrs. Elliott's Housewife.—By Mrs. Sarah A. Elliott: Orange Judd Company, New York. Those who have been much in the Southern States are aware that, in many respects, domestic matters are very different from those in Northern homes. This is especially noticeable in the table, not only in dishes, the raw materials for which are peculiar to the South, but in peculiar methods of cooking articles that are common everywhere. Mrs. Elliott's book does not claim to be exclusively on Southern cooking, but it contains many Southern methods, which are not to be found elsewhere. The Southern house-keeper, being usually far from good markets, gives more attention to salting and smoking meats, than her Northern sister, as well as to preparing pickles and preserves. In these preserving and pickling days, the Northern housekeeper will find in the work methods of preparing various peculiarly Southern compounds in these lines. The useful hints upon various points in household management, add to the value of the book. Price, post-paid, \$1.25.

The Grape-Growers Guide.—By William Chorlton: Orange Judd Company, New York. If persons of means, or of sufficient leisure, were aware how readily large clusters of delicious exotic grapes could be grown in a cold graperie, such grape houses would be more frequent than they now are. We can raise such excellent grapes in the open air, that there is less inducement here to build glass houses than in England. There it is grapes under glass, or no grapes at all. Those who would add to their luxuries by growing exotic grapes, will find Mr. Chorlton's work what its title claims it to be—a guide. Not only is it a guide in growing and fruiting the vines, but in the construction of the house also. Its directions are those of one whose long and successful experience enables him to teach others, and to guide the novice in every detail. Those who propose to erect grape houses, whether cold graperies or those to be heated, will find autumn the most favorable time for the work. Price, post-paid, 75 cents.

American Grape-Growing and Wine Making.—With added chapters on the Grape Industries of California, by George Husmann: Orange Judd Company, New York. In this work the author gives his own large experience, and the methods of others, in cultivating grapes on a large scale. If one has but a few vines, a little more or less time expended upon them, is of no great consequence. In vineyard culture, where vines are to be dealt with by hundreds and thousands, it is necessary to treat them with a view to saving time. The method of training here proposed is that which will produce the best present crops, and also secure the future productiveness of the vines. The instructions for wine making are full and plain, and if intelligently followed cannot fail to produce good results, whether upon a large or a small scale. Those who contemplate undertaking grape culture in a wholesale way, should recollect the importance of making their preparations in the fall; at this time the land should be plowed, even if it is not expedient to plant it. Sent post-paid, \$1.50.

French's Farm Drainage.—By Henry F. French: Orange Judd Company, New York. Judge French, of New Hampshire, was in this country one of the pioneers who "buried crockery" with most excellent results upon his lands and crops. He was certainly the pioneer author, and his practical work upon Farm Drainage, in its way, contributed largely to the improvement of our agriculture. While the work is especially devoted to tile draining, which in the end has proved less costly than any substitutes or make-shifts, yet there are at times cases where it is expedient to make use of drains of wood, of stones, of brush, and even of open ditches. It is well to know where these substitutes for tiles are advisable, and how to construct them in the most effective manner. Over a large portion of our country, autumn is the most favorable season for draining. The soil retains a genial warmth, and the work may often be continued far into the winter. Price, post-paid, \$1.50.

How to Hunt and Trap.—By J. H. Batty: Orange Judd Company, New York. The value of this work consists in its being the record of personal experience, and in its attention to the small matters upon which success, especially in trapping, so much depends. It is too often the case, that those who write works assume that the reader knows about the apparently trivial

matters, and omit the very things which the novice wishes to know. All Mr. Batty's directions show that he has been able in writing for the novice to "put yourself in his place," and anticipate the difficulties he may meet with. Abundantly illustrated. Price, post-paid, \$1.50.

The Cattle Disease at the West.

While the accounts by telegraph and by mail agree that a fatal disease has appeared among cattle in Kansas and Nebraska, they differ as to its nature. Some assert that the dreaded and fatal Texas fever is among the herds in transit, others claim that the mortality is due to bad water; that good water has been very scarce along the route, and the animals have been obliged to drink water so highly impregnated with alkaline compounds, as to prove fatal to many that drank it. The arrival at the Chicago stock yards of several car-loads of sick and dying animals, naturally caused alarm, for fear that the disease would spread eastward. The prompt measures taken at Chicago and other points, resulted in the isolation of the animals that had been exposed to the disease, and the shooting and condemning of the carcasses of those hopelessly sick. It is claimed by good authorities, that the Texas fever can not be communicated by mere contact of the sick with the well, but only when well animals graze after or feed after those having the fever. It is asserted that, should it prove to be the Texas fever, there is no cause for alarm, as the disease prevails to no greater extent than it has for a number of years at this season. A still greater assurance is afforded by the action of the leading cattle men, those at the head of the largest Cattle Live Stock Associations and Cattle Companies at the West, and the railroads. These have agreed to move no more Texan Cattle until after the frost, which removes all danger. The prompt action of the Governors and the official veterinarians in the States most interested, should allay all fears that the disease may spread eastward.

Something New in Ramie Culture.

Many of our readers will recollect with what hopes the cultivation of the Ramie, or China Grass Plant, was undertaken some twenty years ago. In the cotton States especially, where planters were ready for some crop that required less labor than cotton, quite large experimental fields were planted. These attempts showed, that there was no difficulty in producing the raw material. But the culture did not extend, and was soon practically abandoned. The plant contains a fine, strong, and beautiful fibre, more like silk than any other; but to free it from the bark and all extraneous matter, by the slow hand process of the Orientals, was not to be thought of. Machines were invented, and those who undertook to grow the fibre, in the hope that these would prepare it for market, were disappointed. The separation of Ramie fibre by machinery failed, and its production ceased. It appears that the matters surrounding the fibres and attaching them to one another, are of a nature that does not allow of their complete separation by machinery alone, but there must be a solvent which will dissolve these, and allow of the separation of the ultimate fibres.

A NEW PROCESS

has just been discovered and patented, which promises to make Ramie culture practicable, as it removes the obstacle which has so long stood in the way of the industry. The bark is stripped from the stems of the Ramie while they are green. It is then passed through a simple machine, which removes the coarser portions of extraneous matter; the operation is completed by boiling for a short time in a solution of chemicals, which dissolves out all the gum and other materials. After the Ramie is washed, it has a slightly yellowish color, but the ultimate fibres are all distinct, and shine with a peculiar lustre. A final bleaching gives the Ramie a brilliant whiteness, and it appears like silk. In order to encourage the growing of Ramie, the company owning the process, offer to purchase the crude bark, merely stripped from the stems, at a stated price, thus removing one of the obstacles to its culture—the lack of a market.

Much is yet to be settled with regard to the plant as a crop. Its Northern limit is not yet well defined. The plant is a perennial, but it will not bear severe freezing; it will probably succeed in New Jersey, though there the roots may need a covering of litter during the winter. Further South, three and sometimes four cuttings can be made during the season. The plant may be raised from the seed; the seedlings, when large enough, being transplanted to the field. It is much more expeditious to plant pieces of the old plants; these, if planted in autumn will become established and be ready to yield a crop next year. We look with much interest upon this new departure in the treatment of Ramie, as possibly adding another to the crops of our varied agriculture, and with sincere wishes for its success.

War in an Apple Barrel.—Just as we are closing the last pages of this issue, we learn that the fruit dealers in Niagara and Orleans Counties, N. Y., have issued a circular to the apple growers, as follows:—

"We desire to state that on and after the first day of October next, we will not buy fruit in barrels of any less size than the present flour barrel, which is made of staves twenty-eight and one-half inches long, with a seventeen-inch head, and a bilge of sixty-four inches in circumference—and our reasons for such a course are as follows: For the past few years, we have, in common with the whole trade, suffered severe loss not only through poorly packed apples, but inferior and very small barrels, which wholly puts our fruit outside of the export trade. It costs no more to transport a full-sized barrel by railroad, canal, or ocean steamer, than a small one, which fact enables the buyer to pay a greater price for fruit packed in full-sized packages."—The dealers, of course, have a right to buy or not to buy, as they please. And the farmers have a right to use the present legal apple barrels, holding one hundred quarts, if they think best. To accuse the farmers and fruit growers of Western New York of "stinginess," because they use the legal barrel, is entirely uncalled for. The dealers have been hasty in their action. They over-estimate their power if they think they can dictate terms to the farmers. So far as we have heard, however, the farmers and fruit growers have not the slightest objection to using the flour barrel size. Why should they have? The only question is whether the dealers will or will not pay an increased price for an increased barrel of good fruit.

The Hydraulic Ram or Water Ram.—This is an apparatus whereby at little expense a constant stream of water from a brook, spring, or pond can be made automatically to pump a small portion of the water to any desired height, within one hundred to one hundred and fifty feet. The essentials are a supply that will fill say an inch pipe, and a fall of five to eight feet, within a short distance. Any first-class agricultural implement or pump house will send circulars with full explanations, giving prices for rams of different sizes, piping, etc.

Fearless Two-horse Power, positively **unequaled** for ease of team and amount of power, and Clover-huller that gives the most **unbounded** satisfaction. With this machine, shown above, as much money can be earned per day as with a Railway-power grain threshing machine. **Try It.** Fearless grain Threshers and Cleaners, Wood Circular-saw Machines, Fanning-mills and Feed-cutters, not excelled by any. Buy the best. Catalogue sent free. Address, **MINARD HARDER, Cobleskill, Schoharie Co., N. Y.**

OFFICE SUPERINTENDENT GENERAL,
GRAND NATIONAL EXHIBITION OF THE
AMERICAN INSTITUTE OF SCIENCE, ART AND
INDUSTRY OF THE CITY OF NEW YORK.

In accordance with the finding of the Judges, the Grand Medals of Excellence and Superiority were awarded the Liebig Company for their Arnicated Extract of Witch Hazel, as being of great value and purity.
CHARLES WAGER HULL,
Superintendent General.

LIEBIG COMPANY'S ARNICATED EXTRACT OF WITCH HAZEL

HAS TAKEN THE
HIGHEST MEDALS AT THE LEADING EX-
POSITIONS,
AND IS PRESCRIBED AND ENDORSED BY
THE MOST EMINENT PHYSICIANS OF
EUROPE AND AMERICA.

"I can indorse your Extracts of Witch Hazel as the best I have ever used. No scientific physician can afford to be without them," says Professor A. C. Cowperthwaite, Ph.D., M.D., Prof. Disease of Women.

"Your Witch Hazel has afforded many of our suffering patients most decided relief," says Dr. James Knight, Surgeon-in-Chief, Hospital for Ruptured and Crippled, Lexington avenue, corner Forty-second street, New York.

"I have used and prescribed your excellent Extracts of Witch Hazel, and can most heartily indorse them as being the best in the market," says Professor John M. Carnochan, Surgeon-in-Chief, State Emigrant Hospitals, Ward's Island, New York.

"Incomparably superior to the trashy articles which are palmed upon the public," says Dr. Duncan Campbell, M.D., LL. D., President College of Physicians and Surgeons of

Ontario; Member General Council, University of Edinburgh, etc., etc.

Professor Sidney Ringer (University Medical College, London, England,) says: "In piles I have found it singularly successful."

Professor Richard Hughes of London says: "I have cured case after case of piles by its use, and, indeed, do not remember to have ever failed with it."

Professor Pattison of London (on Diseases of Women) says: "It possesses a peculiar power in painful monthly flow. It wards off the suffering without in any way checking the proper and natural flow."

Professor Wm. C. Richardson of St. Louis says: "It gives the most marked relief in Rheumatism."

Hundreds of equally emphatic endorsements from medical men, irrespective of school or belief.

It will also be found efficacious in Monthly Suffering, and female weaknesses generally. Neuralgia, Scrofula, Skin Diseases, Sores and Ulcers, Burns, Scalds, Sore Breasts, Scald Head, Kidney and Bladder Affections, Pain in the Back, Mumps, Sore Throat, Varicose Veins, Diarrhea, Dysentery, Salt Rheum, Sore Eyes, etc., etc.

Beware of worthless imitations.

Sold in Fifty Cent sizes.

Pint size for One Dollar.

Quart size for One Dollar and Seventy-Five Cents.

Still cheaper by the half gallon or gallon.

ARNICATED EXTRACT OF WITCH HAZEL

IS ALSO AN UNEQUALED LINIMENT AND MED-
ICINE.

For Diseases of Horses, Mules, Sheep,
Cattle, Swine, Dogs, and other
Live Stock.

General Wm. T. Withers, the celebrated Blooded Stock Raiser and Proprietor of the Fair Lawn Stock Farm, Lexington, Ky., says: "It should be in every stable in the country."

Col. McDaniel, Proprietor of the celebrated Stony Brook Stud Farm, Princeton, N. J., says: "I hardly think too much can be said in praise of this invaluable medicine for the horse. I should advise all horsemen to keep it constantly on hand."

Abe Straus, Esq., of Lexington, Ky., also celebrated as a Blooded Stock Raiser, says: "I recommend it to all my friends. It has been used in the 'thoroughbred horse' stables of H. P. McGrath, R. H. Owens, Lee Paul, W. B. Scully and other well-known breeders and trainers, and they all pronounce it the best lotion for the horse which they have ever used, giving almost instantaneous benefit."

Professor J. M. Heard, M.D., of New York City, Member Royal College of Veterinary Surgeons of England, Graduate of the London Veterinary College, Professor of Clinical Surgery and Surgical Pathology of the Horse in the N. Y. College Veterinary Surgeons, etc., etc., says: "I take great pleasure in bearing testimony to the valuable properties possessed by the Arnicated Extract of Witch Hazel as prepared by you (the Liebig Co.) No Veterinary Surgeon or horse owner can afford to be without it."

It speedily cures most of the commoner ailments of live stock. Keep it in the house, and you will have it when needed, and you will certainly find it a profitable investment. Many a valuable animal will be saved by its timely use. The testimony of eminent Physicians, Veterinary Surgeons, Blooded Stock Raisers and others, as well as a century of use, has proved beyond dispute that it is an invaluable remedy and liniment for man or beast.

FARM CONVENIENCES.

A PRACTICAL HAND-BOOK FOR THE FARM.

Published, February 20, 1884.

Over Two Hundred Illustrations describing all manner of Home-made Aids to Farm Work. None of these Contrivances are patented, and all farmers can readily make most of them for themselves.

A Manual of what to do and how to do it. Made up of the best ideas from the experience of a large number of practical men. Every one of the two hundred and forty pages and two hundred engravings, teaches a lesson in itself in Farm Economy.

This invaluable book contains simple and clear descriptions of labor-saving devices, for all departments of Farm Work. It abounds in important hints and suggestions, to aid farmers in the construction of these labor-saving devices. The volume is, so to speak, a complete hand-book for doing every-day work quickly and readily. Among the many subjects treated are:

Bins for Oats,
Movable Hen's Nests,
Hints for the Work-shop.
Business Habits,
Relief of Spavin,
Tool Boxes,
Watering Places for
Stock,
Doors,
Harrows,
Feed Racks for Sheep,
Stalls,
Cements,
Prevent Washing of Hill-Sides.
Unloading corn,
Lime and Lime Kilns,
Mixing Cement,
Fastenings for Cows.

Management of Young
Bulls,
Boat Building,
Hay Racks,
Manure,
Making Hinges,
Shaving Horses,
Ventilating Fodder
Stacks,
Clearing Lands,
Troughs,
Hog Killing,
Improved Dump Carts,
Stone Boats,
Fall Fallowing,
Ringing and Handling
Bulls,
Racks for Sheep.

Price, Post-Paid, \$1.50.

HOUSEHOLD CONVENIENCES

Fully Illustrated with Over Two Hundred Engravings.

Published, February 20, 1884.

Every House-keeper can save many times the cost of the work, by providing herself with a long list of cheap, easily constructed labor-saving devices. The secret of success in house-keeping is knowing how to do things quickly and well. "Household Conveniences" is a key to this secret.

A Most Complete Volume, filled with Valuable Hints and Suggestions, for doing all kinds of Work in the Household.

None of these Contrivances are Patented, and all Housekeepers can readily make them for themselves.

CHAPTER I.—ABOUT THE HOUSE.

Hammocks and Tents, Garden Seats, Window Screens and Awnings, Clothes Lines, Ash Bins and Ash Sifters, Wood Racks, Disposal of House Slops, Crematories, Snow-Plows, Leaches, Lye and Soap, Screens, Carriage Steps, Vines at the Door, Cisterns, Fruit Driers, &c., &c.

CHAPTER II.—THE CELLAR.

The Cellar in General, Musty Cellars, Ventilating a Cellar, Ice Boxes or Refrigerators, Preserving Ice, Meat Safes, Water Filterers, Milk Cupboards, Cheese-Presses, Butter Stamps, Cellar Windows, Coal Bins, &c., &c.

CHAPTER III.—THE KITCHEN.

Flour-Boxes, Spice-Boxes, Folding Ironing-Tables, Side-Tables, Bread or Kneading-Boards, Baking-Tables, Wash-Benches, Wash-Sinks, Graters and Slicers, Clothes-Driers, Summer-Drinks, Cooling-Frames, Coffee-Mills, Neat Wood-Boxes, &c.

CHAPTER IV.—PANTRIES AND CUPBOARDS.

Chimney and Corner Cupboards, Well Arranged Pantries, Poison Boxes, Store-Room Boxes, &c., &c.

CHAPTER V.—THE DINING ROOM.

Cases for Silver, Convenient Side-Tables, Table Decoration, Inexpensive Decoration Generally, Extension Leaf for a Common Table, How to Carry, Fruit Cans.

CHAPTER VI.—THE SITTING ROOM.

Plant Shelves, Rustic Window Boxes, Picture Frame, Vines in Window, Decorative Art, Flower Boxes, Hanging Baskets, Care of Carpets, Carpet Sweeping, Hat Racks, Stove Pipes, Lamp Shades, Canary Birds, Ornamental Wood Boxes, Paper Holders, &c., &c.

There are other Chapters on the Library, the Sewing Room; &c., &c.—all making the most exhaustive work of the kind extant. The Volume abounds in common sense hints and suggestions from scores of experienced house-keepers, is within the reach of all, and should be a daily consulted work in every home.

Price, Post-paid, \$1.50.

THE NEW AMERICAN Dictionary.

A Most Valuable Volume.

A Concentrated collection of most useful information, including a **Pronouncing DICTIONARY**, of upwards of **50,000 WORDS**, with their Definitions and accurate Pronunciation, a Beautifully Bound Volume, of

600 PAGES—1,000 ENGRAVINGS.

Fully as good for all practical every-day purposes, as Webster's Unabridged Dictionary.

See what it contains:

1st.—The Dictionary itself, given in **300** pages (3 columns in each page), supplies all the ordinary wants of a Family or Personal Dictionary, and is fully worth the price of the whole book.

2nd.—The next three hundred pages embrace **Forty-five pages of Engravings, illustrating a great number of Animals, Birds, Fishes, Plants, Implements, etc. Over one thousand in all.**

It likewise embraces, among others, the following very useful and valuable facts:

AUTOGRAPHS of all Presidents of the United States.

Explanation of all the 34 words used in the METRIC SYSTEM, now coming into general use in this country, such as *Metre, Centimetre, Litre, Hectare, etc.*

Alphabetical List of American Geographical Names, with their Pronunciation, Derivation, and Meaning.

Popular Names of States and Cities, as "Buckeye State," "Hawkeye State," "Keystone State," "Hoosier State," "Monument City," etc., and why so called.

How to Pronounce Difficult Words. (30 pages.)

Many Valuable Suggestions on How to Speak with Elegance and Ease. (24 pages.)

List of a great number of Slang and Vulgar Words and Phrases to be avoided. (24 pages.)

The History of the United States Flag.

The Area and Population of each of the United States and Territories at each Census from 1790 to 1880.

United States Public Lands—the Amount in each State and Territory; where situated; places of all the Public Land Offices, etc.

Public Land System of the United States.

About Free Homesteads on the Public Lands.

Each year's Prices, for 53 years, of Wheat, Flour, Corn, Cotton, Beef, Hams, Butter, Sugar, Coffee, Bar and Pig Iron, and Coal.

History of American Petroleum.

Tables for reckoning Interest at 4, 5, 6, 7, 8, and 10 per cent, from one day to one year, from \$1 to \$1,000.

Weights and Measures of the United States and of other countries.

Metric System of Weights and Measures, in full.

Vocabulary of Business, giving an Interesting and Useful Explanation of 340 Words and Terms used in Business, such as "ad valorem," "Broker," "Checks," "Days of Grace," "Drafts," "Ejectments," "Foreclosure," "Guarantee," "Invoice," etc., etc. (8½ pages.)

How to Organize and Conduct Public Meetings, Useful Suggestions.

Legal Weight of a Bushel in the different States.

Number of Plants that will Grow, and the Quantity of Seeds to Use on Plots of Ground.

Table of Wages by the Day.

Convenient Tables for Reckoning Wages.

Price, Post-paid, \$1.00.

A GRAND OPPORTUNITY

WHICH WILL NOT BE REPEATED.

A Valuable Book for Yourself, and Three Months Subscription for your Friend for Nothing.

Onward and upward is our motto. We believe that the *American Agriculturist* holds such a place in the affections and regard of its subscribers, that we can confidently call upon them to act individually in aiding us to double its circulation. As an inducement for each subscriber to put forth a little individual effort during the next thirty days, we make the following extraordinary offer, which will **not be repeated**: To every present subscriber of the *American Agriculturist*, English or German, who sends us the name of a new subscriber for 1885 and \$1.60 before the 1st of October, we will present, post-paid, any one of the three valuable books described on the preceding (394) page. Furthermore as an inducement which you can use in assisting you, we will give to every such new subscriber whose name is sent by a present subscriber before October 1st, **the remaining months of 1884 free.**

To recapitulate: Every present subscriber who sends us a new subscription before October 1st, 1884, and \$1.60 (being the regular subscription price, and ten cents extra for postage on the book) will receive, post-paid, any one of the three books described on the preceding page. We offer these extra numbers, not because the yearly price of subscription is not far less than that of any similar journal in the world, and not because every issue of the *American Agriculturist* is not richly worth the price of a year's subscription: but in order to **aid our present subscribers in securing new subscriptions** among their friends and neighbors. If you are able to tell them that they can have the remainder of the year for nothing, you can the more readily persuade them to subscribe; or for the *American Agriculturist*. We do not employ regular agents as is the custom with many other papers, but we follow this plan, one which we adopted many years ago for inducing our subscribers to work for us, and at the same time to reward them for so doing. We shall appreciate any efforts made on the part of our subscribers to extend the circulation of the *American Agriculturist*, promising that the great improvements which have taken place during the past three months, will not only continue, but that other writers and other departments will be added from time to time during the coming year.

Better renew your **own** subscription at the same time, thus ensuring the early and correct entry of your name for 1885, and avoid the danger of error, which sometimes occurs during the hurried, rushing days of the closing year. Publishers of the *American Agriculturist*, 751 Broadway, New York.

The Great West.

All subscribers of the *American Agriculturist* in the far Western States and Territories, who desire to make known to other subscribers the attractions of their localities, and are willing to answer letters on the subject, can use the *American Agriculturist* as a medium of communication for the next three months **without cost**. Write us very briefly covering the following points:

- 1st.—Your name and post office address in full.
 - 2nd.—The character of the land in your neighborhood.
 - 3rd.—Is there any Government land unsold in the vicinity?
 - 4th.—What is the price of improved land?
 - 5th.—What is the price of wild land, if any?
 - 6th.—Is there any railroad near you, and if so, how near?
 - 7th.—The population of your County
 - 8th.—The character of the population.
 - 9th.—Is there any foreign population, and if so, from what countries mainly?
 - 10th.—Are there any churches in your neighborhood, and if so, what churches?
 - 11th.—Are there any schools in your vicinity?
 - 12th.—What is the cost of lumber in your neighborhood?
 - 13th.—Can purchasers buy land on time, and if so, how much time is given?
 - 14th.—Are there any railroad lands in your vicinity, and if so, on what conditions are they sold?
- Address your letter to *American Agriculturist*, 751 Broadway, N. Y.

The Grand Extra Edition

of the *American Agriculturist* for all persons who, though not now subscribers of the *American Agriculturist*, have been subscribers within the past ten years, will be ready in a few days' time. It will be mailed free. Any old subscribers whose post office addresses have changed, will please notify us of the fact, as many are now doing.

Furthermore, to the end that all ex-subscribers may get this Grand Double Number, will every present subscriber please immediately send us on a postal card, the names of every friend and neighbor who, though not now, has sometime been a subscriber of the *American Agriculturist*.

Pleasant Announcement.

Mr. Joseph R. Folsom, until this month a member of the firm of G. P. Putnam's Sons, will hereafter be associated with the Publishers of the *American Agriculturist*, in advancing the interests of that journal, and more especially in enlarging the number, and pushing the sales of our already large list of publications. For eleven years Mr. Folsom has been trained in the old and highly esteemed Publishing House of Putnam, and during the past six years of that period has been a member of the firm. He is a graduate of the Sheffield Scientific School of Yale College, and by travel, study, and business experience, is peculiarly fitted for this field of labor, whose limits we are now materially extending.

Missing Numbers.

Never before was the *American Agriculturist*, printed so regularly, mailed so promptly, and delivered so satisfactorily as now. Thanks to the kind aid of Postmasters and other friends, mailing irregularities resulting from treachery to this establishment which will be fully exposed at the proper time and place, have been adjusted, and now—what before was unknown—there are no complaints to speak of in connection with our extensive Mailing Department. We propose to have this state of affairs continue, and to that end we will thank every subscriber to immediately notify us if his *American Agriculturist* does not reach him as regularly as clock work.

Editors, Club-Raisers, Canvassers, and Subscribers, will oblige us by continuing to forward documents and letters, indicating that any subscription lists, or lists of club-raisers belonging to this Establishment, may have surreptitiously been made. The Postal Album scheme has been pretty thoroughly ventilated all over the country, and we shall thank all our friends to aid us in exposing any similar fresh scheme for either securing the subscribers of this journal or impairing the good will of this Company. The very fact that letters are marked "Private," should not, when the purpose is so clearly transparent, deter the receiver from forwarding them to us if they are kindly disposed to do so in the future.

Features of this Number.

The August *American Agriculturist* was universally pronounced the ablest and most attractive number ever issued. We confidently believe, however, that the present (September) issue will be regarded by readers as superior even to the August number. It embraces over 100 columns of original, illustrated reading matter, and over two hundred different editorials, prize papers, and plain, practical, common sense articles, and topics pertaining to the Farm, Garden, and Household, written expressly for this journal by over 40 different writers. The New Elm Tree Pest; The New Swine Poisoner; The New Early Cherry; The New Narcissus; The New Destroyer of the Cabbage Worm; The New Method of Blanching Celery; A Little Known Grass; together with all other new topics are fully treated and illustrated. Joseph Harris gives a world of information in his "Walks and Talks," and discusses the Apple Barrel War. Dr. George Thurber writes with more than his accustomed interest on a variety of matters, particularly interesting to the horticultural world. Col. Mason C. Weld narrates at length the results of his experiments in testing famous butter cows. Andrew S. Fuller discourses upon the Influence and Effects of Pollen. Professor Thompson, of Nebraska, tells how to most advantageously raise cattle in the West. Elias A. Long presents full instructions for making handsome lawns. Henry A. Haigh gives valuable suggestions in making farm contracts. Professor Slade, of Harvard University, tells how to successfully treat Animal Ailments. Col. F. D. Curtis speaks of Weaning and Feeding Young Pigs. R. G. Newton, Dak., turns the Farmer's Grindstone. Alfred Trumbull analyzes the Harvest of the Sea. Timothy Bunker descends upon the "yaller dog" in his usual facetious vein. Dr. Byron D. Halsted points out the value of buckwheat as a farm crop. David W. Judd, who has been making his accustomed annual tour through the Far West describes what he saw and heard. The illustrations and engravings, by leading artists, number over a hundred—of the full page illustrations, the one representing a Gathering Storm is most vivid and life-like.

Apply at Headquarters.

A Western newspaper asks the public to forward any information about its editor which the public may have. If it will apply at this office, 751 Broadway, N. Y., the paper in question can procure all the information it may require, documentary and otherwise, either with or without "original envelopes."

---------------	---------------	------------

Curing Sumach.

The following is the Virginian method of gathering and curing sumach for market: The leaves are stripped by hand from the branches of the bushes where they stand, and thrown into baskets. Care must be taken to keep the leaves clear of twigs, litter, and the bunches of sumach seed, which are often abundant upon the bushes the latter part of summer.

The filled baskets are emptied into a cart or wagon, which stands ready, and the leaves are taken at once to the curing yard, where they are spread upon low scaffolds to dry. The green leaves should not remain in bulk any length of time. Nothing begins to heat sooner than green sumach leaves, even when in very small heaps. A basketful will acquire a sensible heat in one hour. It is therefore necessary to dry them quickly, to prevent heating and spoiling.

Spread the leaves thinly on the scaffold. By the second day, if the weather is clear and hot, the contents of two scaffolds may be placed on one, thus providing room for more fresh leaves. The leaves will cure enough to house in bulk in three days of fair weather. It is best to have the scaffolds under trees or other objects to shade the sumach while curing, as thus a finer color is imparted to it.

It takes several pounds of the green leaves to make one when cured, and a person must be nimble if he gathers enough in a day to make a hundred pounds of dried sumach. The price paid for cured leaves here, does not make the business very profitable. We were paid one dollar and a quarter per hundred pounds last year, shipping it in bags eighty miles to Richmond. The cost of bags, freight, cartage, etc., is to be deducted from the selling price named. The curing season coming, however, at a comparatively leisure time, there is some margin for profit, and our country people may well turn an honest penny at this small industry. The plant grows wild, and requires no cultivation or care. The collector here only cures the leaves, and sells them thus to the grinders, who have their mills and warehouses in the cities of Petersburg, Richmond, etc. If collectors had the means for pressing the cured leaves into bales of small compass, so as to save room in transportation, farmers at a distance from the markets could well afford to collect and cure sumach leaves for shipment. Those having cotton or hay presses should use them to advantage.

VIRGINIAN.

The Corn Worm.—Mr. J. H. Robinson, Barry County, Michigan. The insect you describe as injurious to your sweet corn, is the caterpillar of *Heliothis armigera*, commonly called the corn-worm. The perfect insect is a moth of a pale yellow color, with olive and brownish markings. The female deposits her eggs upon the silk of the ear, and the young caterpillars soon hatch and make their way to the grains beneath the husks. When the worms are within the husks, no remedy can be applied. All work with this pest must be of a preventive character. The same insect attacks the cotton bolls in the Southern States, where it is known as the "boll worm." It is also destructive to the tomato crop, and will feed upon hemp, peas, string-beans, and various plants of the flower-garden. Traps consisting of lanterns placed in a shallow pan holding water, with a little kerosene floating upon it, have been used with good results. These night-traps need to be set early in the season, when the moths first appear, and before the eggs have been deposited. All worms found in the ears of corn or elsewhere, should be destroyed.

Pedlars and Ring-board Men supplied with

Walking Canes.

All goods sent and delivered promptly, by express C.O.D., or on receipt of Postal Order, to any part of the United States. Two to Five dollars required in advance on orders from parties who are not regular customers.

Practical Forestry.

A Treatise on the Propagation, Planting, and Cultivation, with a Description, and the Botanical and Popular names of all the

Indigenous Trees of the United States,

BOTH EVERGREEN AND DECIDUOUS, WITH NOTES ON A LARGE NUMBER OF THE MOST

VALUABLE EXOTIC SPECIES.

By **ANDREW S. FULLER,**

AUTHOR OF THE "STRAWBERRY CULTURIST," "GRAPE CULTURIST," "SMALL FRUIT CULTURIST," ETC., ETC.

ILLUSTRATED.

In his Preface, the author says: "Many a time during my life have I felt the need of some one volume of moderate size, containing the names and descriptions, however brief the latter might be, of all the trees indigenous to the United States. Having waited in vain for the appearance of such a book, I have attempted to write one myself, with the hope that it will be of service, not only to those who may desire to raise forest trees for pleasure or profit, but to others, who, like the author, may occasionally visit different parts of the country, and need some such guide, that will help them to call to mind the names, as well as to assist in identifying the different species of trees to be found in our forests. I have written it for those who are not supposed to have given the subject of forestry any special attention, and for this reason purposely avoided using any greater number of scientific and unfamiliar terms than was actually necessary in describing the various species and varieties. Furthermore, at the suggestion of the publishers, I have been as brief as possible, in order to make a book that can be sold at a price within the means of all, and one that will not even deter the summer tourist, who is about to spend a few days or weeks in the country, from dropping a copy into his grip-sack before leaving home."

WE LAMBS,

YEARLING EWES,

BREEDING EWES,

For Sale at Very Low Rates

My sheep have little or no grain. They are kept in moderate breeding condition. They have proved themselves good breeders and are healthy, useful sheep, such as I can confidently recommend to all readers of the *American Agriculturist*. There never was a better time to buy.

Address **JOSEPH HARRIS,**

Moreton Farm, Rochester, N. Y.

SAM'L BURNHAM, *Secretary.*

REMEMBER —THE— MICROSCOPE.

The great delight with which the **New American Agriculturist Microscope** has been received and used by those who have secured it, as shown by many letters which have come to us, assures us that it is a favor to our readers to call their attention to it, and to the ease with which it can be secured.

Every member of the household, young and old, finds enjoyment and instruction in this valuable little instrument. The fields, the trees, the streams—almost everything around us affords objects which may be examined with interest.

The *American Agriculturist* for March, contains a full description of this new and beautiful Microscope.

If you have not this number of the paper, and would like to see the description, write to us, and we will forward it to you. This Microscope is sent, delivered free, by us, to any part of the United States and Territories for \$2—and delivered free to any actual subscriber of the *American Agriculturist* for 1884, for \$1.25. Furthermore, we will present one, delivered free, and send the *American Agriculturist* to any new subscriber, post-paid, for \$2. Still further, we will present this Microscope to any present subscriber, delivered free to him, if he sends us two new subscribers to the *American Agriculturist* for one year, at \$1 50 each.

Friends of Agriculture.

Mr. Lawson Valentine.—We infer from pleasant letters received from Mr. Lawson Valentine, during his European journeys, that he is collecting a large amount of valuable information, which, on his return to the United States, will be utilized at Houghton Farm and elsewhere, for the benefit of American Agriculture. His latest letter, received as we go to press, speaks of his going to Switzerland with his family.

Mr. D. D. T. Moore.—The friends of D. D. T. Moore will be pleased to learn that he contemplates starting a new journal. Mr. Moore failed at the height of his prosperity, because he had distributed his means in too many other channels. He preferred to fail honorably, rather than get money by hocus statements of his actual condition—from relatives, employees, poor ministers, hard-working printers, and the public generally—and then decamp to other parts. He is still here in New York, and we shall publish an interesting article from him next month.

Mr. J. S. Woodward.—We welcome Mr. J. S. Woodward to New York journalism. Mr. Woodward has the enviable reputation of being a high-toned, honorable gentleman.

See Pages 304 & 395.

GRATEFUL-COMFORTING.

EPPS'S COCOA.

BREAKFAST.

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately-flavored beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—Civil Service Gazette.

Made simply with boiling water or milk. Sold only in half-pound tins by Grocers, labelled thus:
JAMES EPPS & CO., Homeopathic Chemists, London, England.

Sedgwick Steel Wire Fence

Is the only general purpose Wire Fence in use, being a Strong Net-Work Without Barbs. It will turn dogs, pigs, sheep, and poultry, as well as the most vicious stock, without injury to either fence or stock. It is just the fence for farms, gardens, stock ranges and railroads, and very neat for lawns, parks, school lots and cemeteries. Covered with rust-proof paint (or galvanized) it will last a lifetime. It is Superior to Boards or Barbed Wire in every respect. We ask for it a fair trial, knowing it will wear itself into favor. The **Sedgwick Gates**, made of wrought-iron pipe and steel wire, defy all competition in neatness, strength and durability. We also make the best and cheapest **All Iron Automatic or Self-Opening Gate**, also **Cheapest and Neatest All Iron Fence**, **Best Wire Stretcher and Post Auger**. Also manufacture **Russell's excellent Wind Engines for pumping water**, or geared engines for grinding and other light work. For prices and particulars ask hardware dealers, or address, mentioning paper.

October.

Season of mist and mellow fruitfulness!
Close bosom friend of the maturing sun;
Conspiring with him how to load and bless
With fruit the vines that round the thatch eaves run;
To bend with apples the moss'd cottage trees,
And fill all fruit with ripeness to the core. KEATS.

Renew Now.

Do not wait, please, until the end of the year before renewing your subscription, but forward your name for 1885, on receiving this number.

A Day Off.

A spirited engraving on the previous page suggests October and a favorite rural pastime.

Bounteous Harvests.

The engraving on page 415 typifies the ripeness and abundance of the season; the in-gathering of the "fruits of the earth," proves this to be almost without exception a year of plenty and fruitfulness.

Rare Premiums.

The Premiums given to our subscribers for efforts on behalf of the *American Agriculturist* comprise a more varied and valuable list than ever before presented by us. We have secured them at great bargains, of which our subscribers get the benefit.

To Our Old Readers and Friends.

Within a comparatively brief period this year, over four thousand subscribers have written us congratulatory letters regarding the *American Agriculturist*. Not only will the great improvements witnessed in the May, June, July, August, September, and October numbers continue, but we are making arrangements for additional writers and additional departments. We have appreciated your support in the past, and with these additions and improvements to the paper, may we not expect you to continue in our great army of readers, and bring many recruits with you for 1885?

Every Subscriber, Club Raiser, and Exchange Newspaper, will please turn to page 436.

Features of this Number.

Joseph Harris, besides his instructive Walks and Talks, has a timely article on "Sheep in Winter," and Gathering Crops.... D. D. T. Moore, long editor of "Rural New Yorker," writes on Agricultural Fairs as Educators.... Adobes, the cheapest building material of the Far West, are described by J. L. Townsend, of Utah.... Remarkable milk and butter records of Holland Cows are given by Dudley Miller.... The ailments of numerous Farm Animals are prescribed for by Professor D. D. Slade, of Harvard University. Col. M. C. Weld tells what he saw "Among the Farmers," and writes on Milk-fever, Sheep, Breaking Colts, etc. Beautifying the Farm is treated by Elias A. Long. David W. Judd continues his notes of travel in the Far West. Dr. Byron D. Halsted writes about "Our Dog" (with portrait), Experiments in Crop Feeding, The Cottonwood Beetle and other insects. The Ripening and Decay of Fruit is treated by Doctor George Thurber, who describes an Entirely New Plum, Japanese Radishes, and has numerous other horticultural articles. Legal points in Hiring Farm Help are made plain by H. A. Haigh. House-keepers will find full directions for making pickles by Aunt Hattie. Ethel Stone gives hints on Table Etiquette, and useful and ornamental articles are illustrated. The Boys and Girls have an illustrated story, the Doctor's Talks, a Dakota Boy's Letter, Puzzles, etc. All interested in the trotting feats of Jay-Eye-See, will be glad to see a portrait of this horse. The full page and other illustrations are executed by such artists as Forbes, Bennett, Scranton.

FARM AND GARDEN WORK FOR

— OCTOBER —

We hope the town, county, district, State, and other fairs, have attracted the merited attention of farmers everywhere. Many of these exhibitions are held this month, and there is still time to east in the sickle of personal attendance, and reap a large harvest of new and valuable ideas. Winter wheat may be sown up to the middle of the month. Where the soil is deep, rich, and mellow, late sowing may be better than early, as the plants thus escape the ravages of the Hessian fly. October sown wheat may be much benefited by an application of a quick-acting commercial fertilizer, which will stimulate the young plants to a rapid growth. Two hundred pounds per acre of either sulphate of ammonia or nitrate of soda may greatly increase the crop.

Where there is a market for husks, the ears of corn may be picked from the stalks and husked in the barn, otherwise it is better to husk the corn in the field. If the seed ears have not been selected, do this important work now. Leave a few of the husks on the seed ears, by which they can be braided and hung up in bunches in a dry place out of the reach of vermin. After husking, bind the stalks in bundles, and set these in large shocks. If this work is properly done, the fodder may stand in the field until winter, and be drawn to the barn as desired. As soon as frosts are expected, the beets must be harvested; next secure the carrots, and follow with the turnips. Roots keep well while stored in pits, if frost does not reach them, and there is sufficient ventilation provided.

Potatoes should have been harvested before now. Gather and burn the tops if Paris green has been used upon them. A general cleaning up around the barns and out-buildings should be made before winter sets in. Keep the teams at work with the plows, hauling swamp-muck, etc. In short, do whatever work that will aid in the coming spring with its pressing labors.

LIVE STOCK NOTES.

Keep the horses in the stables at night. The season is now too far advanced for night-pasturing. A cold storm might do exposed horses much harm. When unavoidably drenched, rub the horses thoroughly and blanket them. Oil the harnesses and keep them clean. The pasture supply of food for cows is now falling off, and green food must be added. The vegetable garden and the root field should furnish wholesome food. It is, however, not wise to feed any waste rubbish to the milch cows. Young stock should be kept in a thriving condition; their future value largely depends upon a vigorous, early growth. Early lambs to those who have the facilities for raising them are always profitable. Weed out the poor ewes, and prepare them for the shambles. Use only pure-blood rams. Plan now for lambs to come in March. Brood sows should be in good condition. Bear in mind that it pays best to fatten and dispose of the hogs before the coldest winter weather comes. Push them now for the early market. Fowls need warm winter quarters provided for them with abundance of wholesome food and pure water. They do not bear crowding closely together in large numbers.

Market and Kitchen Garden.

Celery, cabbages, spinach, etc., should have their late growth aided by keeping the soil loose and free from weeds... Green weeds should go to the compost heap—stakes, brush, and what rubbish will burn, to the burn heap; stones, tin-cans, and other incombustibles should go to a pit made for the purpose.... Cut the asparagus tops when they begin to turn yellow, and burn. Do not scatter the seeds.... The celery crop is to be "handled" late this month by bringing the stalks erect and keeping them so by drawing earth to the base.... Turnips, parsnips and salsify are not injured by frosts; beets and carrots lose sweetness by freezing.... Thin spinach that is to be wintered by cutting out plants for present use.... Dig sweet potatoes as soon as the frost touches the vines. Handle carefully, and store in barrels or boxes.... If frost is feared, collect the squashes in heaps and cover with the vines.... Tomatoes are injured by frost. A few vines, when frost is threatened, may be pulled up, all the very green fruit cut away, and the plant with partly ripened fruit hung up in the barn or elsewhere, under cover.... Divide old rhubarb roots with a bud to each piece, and plant in very rich soil, four feet apart each way.... Sage, thyme, and other sweet herbs, may be cut, tied in bunches, and hung in the shade to dry. Cutting every other plant will give the rest room to grow.... Cold-frames should be made ready to receive cabbage, cauliflower, lettuce, and other plants.

The Fruit Garden.

Blackberries and Raspberries start very early, fall planting is preferable. The tips of Black-ears that touch the ground should be held in place by a little earth. To propagate from root cuttings, cut the roots into pieces two or three inches long, and place in a box with alternate layers of roots and soil. Bury the box in a dry place, below reach of frost.... After the currant and gooseberry leaves fall, prune. Make cuttings of last summer's growth, and plant at once.... Keep strawberry beds clear of weeds, cut off runners from those planted last summer, and cover the soil with straw.

Flower Garden and Lawn.

The lawn should not be cut too closely; leave it long to protect the roots in winter.... If geraniums and other tender flowers are protected from early frosts, they will continue in bloom for some weeks. Protect with newspapers, light cloths, or leafy boughs.... Plants to be potted should be taken up in time to be established before cold weather. Plant the Holland bulbs as early as possible. See article on page 423. Tender bulbs, such as gladiolus, tiger-flower, tuberose, etc., should be taken up, dried, labeled, and stored. Lift cannas before frost kills the tops.... Perennials may be taken up, divided, and reset in new places.... Chrysanthemums to bloom in the bed will need stakes; to those established in pots, give weak liquid manure.... After the frost has touched the dahlias tops, cut away, and dig the roots on a dry day. Store in any place that will keep potatoes.

Greenhouse and Window Plants.

Have the house in readiness to receive the plants. Tender tropical kinds may go in before cold nights check them.... Plants for the window may be set on a veranda at first. Repot any that need it, and see that all are free from insects—have the pots clean.... Pot bulbs and plants to be forced, and give a rest of some weeks in a dry cellar.... Fill window boxes and hanging baskets early, and have the plants well established before taking in.... Ivy is the best climber for general use. Canary-bird flower to be raised from seeds, is effective.... Annuals for blooming during the winter, may be sown now and every two weeks.... Supplies of soil, sand, moss, pots, and whatever else that is likely to be required for greenhouse or window plants in winter, should be laid in now.

Bee Notes for October.

W. Z. HUTCHINSON.

PREPARATIONS FOR WINTER.—If bees require feeding, there should be no delay. Bees are ready for winter when in chaff hives, i. e., double-walled hives, with a pillow or cushion of chaff, forest leaves, or other absorbent, placed in the upper story. Bees that are to be wintered out of doors in single-walled hives, need some additional protection, and it should be given at once, that the bees need not be disturbed after they have settled themselves for their long winter nap. We know of no cheaper or better method of protecting bees upon their summer stands, than that of surrounding the hives with several inches of chaff, sawdust, planing-mill shavings, forest leaves, or other material that is a poor conductor of heat. To keep the packing in place, a box of rough boards without top or bottom, one foot larger each way than the hive, should be set down over the hive, the lower edges on three sides resting upon the ground, while the front end is enough narrower to allow the hive stand *a*, figure 1, and front end of the lower board, *b*, to slightly project. The strips of wood, *c, c*, are three-eighths inch thick, and seven-eighths inch wide, the back ends of which are thrust a short distance into the entrance of the hive. A thin board, *d* (a piece of shingle will answer), is tacked to the upper sides of the strips *c, c*, and extends back until it comes in contact with the front of the hive above the entrance, thus forming a support to the sawdust or chaff above, and furnishing the bees with a passage-way underneath. A narrow piece of thin board, *e*, is tacked under the front ends of the pieces *c, c*, and extends back to the front end of the bottom board, thus furnishing the bees with an alighting-board. The queen-excluding honey-board should be turned over, thus forming a three-fourths-inch space above the frames, which will allow the bees to readily pass from comb to comb. Over the honey-board should be spread a piece of burlap, or old carpet. One of

Fig. 1.—A BEE-HIVE WINTER COVER.

the cases for holding sections should be placed over this covering, filled with some of the packing material, and covered with the regular hive cover. A shingle nail is laid under each corner, to allow the escape of moisture. The next step is to fill with chaff or sawdust, the large box surrounding the hive. Some of the packing material will run out around the front of the hive, but this does no harm. It would, perhaps, be better if it was banked up in front of the hive until there was only room for the bees to pass. After the box is filled, it can be covered with a "shade-board," kept in place by laying a stone upon it.

In some respects this method of wintering is superior to all others. If a warm day occurs in winter or early spring, the bees can enjoy a purifying flight. The protection enables the bees to raise large quantities of brood early in the season. These hives are less expensive, and more easily handled than chaff hives. Bees in them are managed with less labor. The sawdust that remains

around the hives after the rough boxes are removed, prevents the grass from growing. The packing should remain around the hives until the weather is warm and settled in spring.

WINTERING BEES IN "CLAMPS."—Wintering bees by burying them in the ground is an old method, practised but little of late, until quite recently. In burying bees, first dig a pit seven feet wide at the top, the length depending upon the number of colonies to be buried, with walls, *a, a*, figure 2, sloping forty-five degrees. Fence posts or stout poles, *b*, are laid across the top, with the ends embedded in the sloping sides, until their upper sides are eighteen or twenty inches below the surface level. The pit is filled with straw, *c, c*, up to the posts; boards are laid upon the posts, and the hives placed in rows upon the boards. After the hives have been covered with a foot or more of straw, poles as rafters, *d, d*, are placed over them, and covered with a layer of straw. A foot or more of earth over the whole, and a drain, *e*, complete the job. A sandy hillside is an excellent location for a "clamp." Probably not more than twenty-five colonies should be buried in one "clamp," unless given considerable room inside, and abundant ventilation. The bees should not be buried until just

Fig. 2.—SECTION OF A "CLAMP."

before the ground freezes for the winter, and not dug out until they can gather pollen.

CELLAR WINTERING.—Bees that are to be wintered in a cellar, should be left out until it is so late that there is no prospect of their enjoying another flight. The cellar needs to be well ventilated, but as to whether the atmosphere should be moist or dry, authorities differ. Keep the temperature of that degree at which bees are most quiet.

Autumn Care of Orchard and Nursery.

The gathering of late fruits will be an important work this month, one which requires more care than is usually given to it. The longest keepers may hang until there is danger of frosts. The color of the fruit, the ripeness of the seeds, the readiness with which the stem of the fruit parts from the tree, and the falling of the fruits, are all signs of ripeness. Winter pears are to be treated the same as winter apples. Do not mix varieties, but give each kind a separate barrel or box. Fruit to be kept, should not be taken to the cellar or fruit house until frosty nights. In packing fruit for market, make first and second qualities, and use all inferior fruit at home. Have the fruit of even quality all through the barrel, using barrels of full size. Always bring the head in place by sufficient pressure to prevent shaking. Cider apples are not injured by light frosts. Placed in heaps the fruit loses water, and the juice becomes richer. Cool weather is best for cider-making. Top-dress orchards to keep up fertility any time this month. Order nursery trees to be planted this fall, or heeled-in for spring planting. Grapes, when quite ripe, hang straight down from the vine, the stem becoming limber. Catawba, Iona, Isabella and Diana grapes, are usually kept by packing in five-pound boxes. Fill from the bottom, using pressure to bring the bottom in place. Expose clusters to the air in a dark room to toughen the skin before packing. Keep the boxes in a low uniform temperature in a dry place. Experiments with keeping grapes with their stems in water, are described elsewhere. Pruning may be done as soon as the leaves fall. New vines may be planted. Top-dress the orchard with fine manure, and throw up a mound of earth around young trees.

Jay-Eye-See.

Having already presented a spirited engraving of Maud S, and her mate Aldine, drawn expressly for us by Edwin Forbes, we herewith give a spirited portrait of Jay-Eye-See, by the same artist. This picture was taken for us by Mr. Forbes just before Jay-Eye-See trotted on the Prospect Park Course, Brooklyn, August 26th, this year, when he trotted a mile in 2:12½. Jay-Eye-See trotted a mile at Providence, R. I., in 2:10, thus beating the then best record of Maud S, the Queen of the turf for over three years. Though dethroned for a day, Maud S subsequently, on the track at Cleveland, O., regained with great elat her former first place by trotting a mile in the unprecedented time of 2:09½. Mr. Robert Bonner, who has recently purchased

There was from the first a strong public sentiment against racing running horses, and the trotter has come up to supply a natural sporting want. The breeding of trotting horses for the sake of great speed upon the race track is not in itself desirable. But by developing quick roadsters the American trotter is doing a good work for farmers and all persons who can use a rapid stepping horse with profit as well as pleasure.

Colts.—Hints about Breaking.

Break and drive colts by using the home-made "rig" often described as a "breaking-cart"—a stout pair of wheels and axle with shafts attached, running out behind eight feet or so according to the height of the wheels. This is to prevent back-

this lets the animal have a view perhaps for the first time what is behind him—and away he goes. Then, the harder the driver pulls, the plainer the horse sees the wagon. In buying a horse, make sure that he is not afraid of the vehicle behind him when in motion. It is easily done by walking at his side and lifting the back part of the blinder.

One of the most important things to teach a colt is to back and to stop backing at the word whoa! This should always be done at first on a gentle down grade. The backing of course must be done down the grade, which should not be steep enough to take the entire effort of backing off of the colt, but to lessen it essentially. As soon as the colt becomes a little accustomed to the cart, or even before he is put in shafts, he must learn what whoa! means, and under any and all circumstances to stop short when he hears it. Then when placed

"JAY-EYE-SEE"—THE FASTEST TROTTING GELDING.

Drawn (by Edwin Forbes) and Engraved for the American Agriculturist.

Maud S from Mr. William H. Vanderbilt, stood ready to likewise purchase Jay-Eye-See from his owner, Mr. J. I. Chase, should he, on the Prospect Park Course, beat the best time of Maud S. His time, however, was not as good, within two and one-half seconds, as he had already made at Providence, the weather and the track both being against him in this race against his previous record. Jay-Eye-See, a black six-year-old gelding, is a remarkable result of the breeding together of horses in whose veins flow the blood of famous trotters. He is the fastest gelding in the world, sired by Dictator, a son of Rysdyk's Hambletonian, both famous trotting horses of the most natural type. Jay-Eye-See is thus a full member of the most celebrated of all trotting families. His sire is a brother of Dexter, the fastest trotter of his time, who beat the best record of Flora Temple for three successive years. These bits of pedigree show that trotting powers are an inheritance, *i. e.*, speed on the track runs in the blood with marked certainty. Americans take an honest pride in their trotters because they are the outgrowth of American ideas.

ing and rearing. In making this breaking-cart, it is best to have the shafts rather close, as the colt is more confined, and soon gives up the natural tendency to turn around. Drive colts barefoot until the feet show signs of wear and lameness, usually until they are five years old. If the aim is to make a trotter of him, and he is given speedy work, that alters the case somewhat, and the hard pounding that some roads give, with the danger arising from striking stones in such a way as to split the hoof, makes it necessary to shoe fast colts when they are undergoing training exercise.

In breaking and training colts single, it is best to do so without blinders. They become quickly accustomed to the appearance of a vehicle following them, which must be a terrific sight to a horse that has always been driven closely blinded, when by chance, having on a headstall with loose cheek-pieces, or by any other accident, he sees a top-wagon following close to his heels. Many a frightful runaway has come from this cause. Long cheek-pieces, when the horse is suddenly drawn up, are naturally thrown out from the head, and

before the breaking cart, some severe "check" should be arranged to be applied at once. Several contrivances are in use. A hard jerk upon the bit is made to take the place of the check, but that makes the tender mouth sore and irritates the animal. Some colt-breakers use a strap rein with a ring in the end, passed over and attached to the head-stall, the end of the rein being run through the ring, which hangs at the right side of the head, and goes back to the hand of the driver. At the word, a sharp pull tightens the noose upon the colt's throat and throws up his head, stopping him at once. It plays loose immediately on being relaxed, and while it gives the colt a palpable hint, it does him no harm. The expectation of the "hint" will soon cause the colt to stop at the word, as if he were struck in the face. The habit thus acquired will last for life, provided the word is not improperly used, and he gets an idea that whoa! means "not quite so fast." Even a runaway horse, properly trained to stop at whoa! will often do so, and the habit is a sure safeguard against accidents, which can hardly be over-estimated.

Feeding and Care of Farm Animals.

PRIZE ARTICLE.—BY "A WESTERN FARMER."

Sheep.

Sheep are profitable if well cared for, but unprofitable when neglected. The middle-wooled sheep will give the best satisfaction to the general farmer. Warm, dry, clean sheds are essential. Allow no other stock to occupy them with the sheep. The feed-racks should be under cover. Feed good hay of any kind, shelled corn and oats mixed, and chopped roots for winter. Cold weather causes the wool to grow rapidly, and a liberal supply of food must be provided so that there will be no "starvation break" in the staple to reduce its value. There is only disaster and loss in short feeding at any time. Bright oat straw cut short, dampened and primed with oat-meal, corn-meal, or oil-cake meal, is very fair feed in the absence of good hay. A strong, sucking lamb, will rapidly reduce in flesh the fattest ewe, unless she is well supplied with the best and richest food. Grass is best, of course, but in its absence, roots cut and mixed with corn-meal, and plenty of good bright hay, will suffice.

Clover and mixed grasses make the best pasturage for sheep. With a hurdle fence, corners and patches of grass, green stuff, aftermath, etc., etc., can be profitably utilized, and the soil enriched. Supply the sheep with plenty of salt when at pasture. See that they never lack water. A trough ten or twelve feet long, twelve inches deep and wide, with a hinged cover having an opening at one end, will keep water clean. Scrub it out occasionally.

Lambs.
